PUBLIC HEALTH REPORTS

Published since 1878

Contents

	Page
Public Health Reports—From yellow fever to international health.....	1
The new Public Health Reports. <i>Leonard A. Scheele</i>	2
The Board of Editors—Public Health Reports.....	3
The CMP and the public's health. <i>W. E. Gilbertson</i>	8
Susceptibility of <i>Anopheles quadrimaculatus</i> to Korean vivax malaria. <i>Martin D. Young and Robert W. Burgess</i>	14
Veneral disease control program in transition. <i>Theodore J. Bauer</i>	17
National morbidity reporting—Revised system. <i>C. C. Dauer</i>	21
Salaries of State health department personnel—From 1947 to 1951. <i>Sam A. Kimble</i>	26
Impact on the Department of Public Health of the San Diego mass chest X-ray survey.....	31
Fluoridation of municipal waters, American Dental Association symposium. <i>Frederick S. McKay, A. P. Black, Milton E. Nicholson, F. A. Bull</i>	36
Leadership and the conditions of organizational effectiveness. <i>Douglas McGregor</i>	42
Observations on the epidemiology of poliomyelitis. <i>W. Thurber Fales and Matthew Taback</i>	47
<i>Trichophyton tonsurans</i> ringworm—A new public health problem. <i>Lucille K. Georg</i>	53
Aquatic invertebrates as indicators of stream pollution. <i>Arden R. Gaufin and Clarence M. Tarzwell</i>	57
Health departments and the housing problem. <i>Ralph J. Johnson</i>	65
Evaluating health education. <i>Andie L. Knutson</i>	73
Studies in penicillin treatment of syphilis—From 1943 to 1950. <i>R. C. Arnold, R. D. Wright, S. Levitan, and J. C. Cutler</i>	78
Leading causes of death.....	90
The practice of public health—PHR conference report of the American Public Health Association annual meeting.....	96
PHS publications.....	120

PUBLIC HEALTH REPORTS

Published since 1878

Contents

	Page
Aging: Implications for public health. <i>Clark Tibbitts</i>	121
The Second International Gerontological Congress—Public health aspects in brief.....	127
Therapy with cortisone. <i>C. Paul Silirie</i>	142
Conjunctivitis in elementary schools—Thomas County, Georgia, 1949–50. <i>Dorland J. Davis and Virginia D. Hines</i>	145
Ideas.....	150
Research in epidemiology of mental illness. <i>R. H. Felix and Morton Kramer</i>	152
Reports to 50th Conference of the State and Territorial Health Authorities.	161
State of the Nation's health services— <i>Scheele</i>	161
Health programs in the Federal budget— <i>Staats</i>	164
New horizons for child health— <i>Eliot</i>	169
Aging—weakness or strength?— <i>Ewing</i>	171
Inventory of health needs— <i>Mountin</i>	173
Community facilities and services program— <i>Pond</i>	175
Day-care services for children— <i>Arnold</i>	177
Korean malaria— <i>Myers, Andrews, and Coatney</i>	178
Dental health— <i>Knutson</i>	180
Heart disease— <i>Potts and Jones</i>	181
✓ Research for improved nursing practices. <i>Lucile Petry, Margaret Arnstein, and Pearl McIver</i>	183
Tuberculosis case-finding survey program of the Veterans Administration. <i>Leo V. Schneider and Morton Robins</i>	189
Terramycin for nongonococcic urethritis and Reiter's disease. Preliminary report. <i>R. R. Willcox and G. M. Findlay</i>	196
Trends.....	200
The practice of public health—PHR conference report of the American Public Health Association annual meeting: Part 2.....	202
PHS publications.....	221
PHS films.....	222

PUBLIC HEALTH REPORTS

PUBLIC HEALTH MONOGRAPHS

are edited and issued by *Public Health Reports* under the general direction of the Board of Editors. The monographs present contributions to knowledge in the fields of public health, particularly material that is extensive, detailed, or specialized. All manuscripts considered for publication as monographs receive the same technical and scientific review as papers submitted to *Public Health Reports*.

Public Health Monographs are listed in the table of contents of the issue of *Public Health Reports* with which they are concurrently published. They are also listed in its annual index, and in the *Quarterly Cumulative Index Medicus* (American Medical Association) and the annual *Armed Forces Medical Library Catalog*.

The monographs replace in whole or in part a number of publications series previously issued by the Public Health Service, including Public Health Bulletins, Bulletins of the National Institutes of Health, Venereal Disease Bulletins, and Supplements to the *Journal of Venereal Disease Information* and to the former weekly *Public Health Reports*.

Each Public Health Monograph is placed on sale by the Superintendent of Documents; series subscriptions are not available, nor are monographs included in subscriptions to *Public Health Reports*.

Contents for August—continued

PHS films-----	787
Family food consumption studies----- <i>C. M. Coons.</i>	788
Drug experience in two programs for medical care----- <i>Herbert Notkin, Bettie Rogerson, Wilfrid Davis, and Matthew Taback.</i>	797
Refuse-can holders----- <i>Ralph J. Van Derwerker and Charles C. Johnson, Jr.</i>	802
Two surveys of disabling illness----- <i>Theodore D. Woolsey.</i>	807
Leptospiral etiology of Fort Bragg fever----- <i>William S. Gochenour, Jr., Joseph E. Smadel, Elizabeth B. Jackson, LaRue B. Evans, and Robert H. Yager.</i>	811
PHS publications-----	814
Public health in the scientific assembly of the American Medical Association. PHR conference report-----	815
Short reports and announcements:	
Environmental health course . . . 724. Vocational rehabilita- tion . . . 746. Nursing study . . . 758. Heart disease facility . . . 761. Dr. Knutson appointment . . . 779. Heart radio series . . . 796. Birth weight data . . . 828.

years ago

in Public Health Reports

THE August 15, 1902, issue of *Public Health Reports* called attention to a "new and strange disease," prevailing in the Bitter Root Valley of Montana—"the so-called 'spotted fever' of the Rocky Mountains." Investigations of this disease by the United States Public Health and Marine-Hospital Service, which were to continue for many years, had begun.

Surgeon J. O. Cobb, of the Service, had been directed by telegram on June 23 to proceed to Missoula, Mont., in order to investigate an outbreak of spotted fever in that district. "The disease was said to be highly communicable and, therefore, a matter of importance to the public health of the country."

Dr. Cobb, who found that Dr. Louis B. Wilson and Dr. William M. Chowning of the Montana State Board of Health had already worked out many of the details concerning the cause of the disease and its method of transmission, reported, in part, as follows:

"For a definite number of years (17) the disease has been known among the local practitioners. . . ." It "has always been limited to the spring months, no case being reported later than July 20, and none earlier than 1 case on uncertain date in January. . . . All clinical experience goes to show that the disease is not contagious or infectious.

It is, therefore, without doubt, an incommunicable disease, as an intracorpuseular parasite has been found constantly present in the blood of each examined case this year. The organism resembles very closely Theobald Smith's Texas cattle fever organism, and it is certainly reasonable to believe . . . that this disease is introduced in man . . . in like manner as in the Texas cattle fever organism, viz, by the tick.

"Now, having found an intracorpuseular organism in the blood of their cases, the next step was to find the host, and here they were astonished to learn that it was a common belief among the people of the valley that the disease . . . was caused by the bite of the tick. Clinically, they found this idea correct, inasmuch as, positively, every patient gave history or showed evidence of being bitten by the tick. . . .

"As hundreds of persons are bitten with ticks throughout this portion of the State, and as a great many are bitten by ticks from this infected locality and comparatively few contract the disease, it was fair to presume that all ticks did not harbor the parasite. This naturally led to the presumption that the host was not the tick, but some animal infested by ticks. If the infected animal were the horse, cow, deer, sheep, or other rang-

ing animal, then one would expect to find the disease gradually spread over a wider area from year to year.

"... they found that the gopher (which in this section is the ground squirrel) was infested with ticks, and it is well known that this animal will not cross water except under extraordinary circumstances. This being true, it would give the necessary explanation why the disease was confined to such a small locality and why its limitation seemed to be so clearly defined. The next step was to obtain a great number of these animals for examination. This part of their work is uncompleted, but they have found enough to make them believe that the gopher of this particular section has . . . become infected with this organism and that it has acquired or inherited immunity.

"A further interesting observation is that the first cases follow closely the appearance of the spring crop of ticks and the disease subsides promptly upon the disappearance of the tick, which is usually about the first of July. This is a very strong point, for laying aside the difference in the clinical features of the diseases which have nothing in common with malaria, it seems nearly positive proof that the mosquito can be eliminated as a factor."

frontispiece

Pictured on the inside front cover is the Charleston Memorial Hospital, under development as a district hospital for the Charleston, W. Va., hospital service area. Its master plan calls for 440 beds, 132 begun in 1949 and 100 now under

construction. The present facilities—including clinical and service activities and an out-patient department—have been in operation since October 1951. In keeping with the hospital service area concept, this institution will pro-

vide for more complete and advanced diagnostic and treatment facilities than are normally possible in smaller hospitals. The Memorial Hospital also houses a branch of the Charleston-Kanawha County Health Department.

Milepost . . .

In October 1948, Surgeon General Leonard A. Sechele dedicated a new hospital at Live Oak, Fla., the first to be completed under the Hospital Survey and Construction Act. In October 1952, Dr. Sechele formally opened a 49-bed hospital at Lebanon, Oreg., the one-thousandth project to be completed under the program.

Of the 1,000 projects now in operation, 525 are completely new hospitals, 330 are additions and improvements to existing hospitals or related facilities, and 145 are health centers. An additional 800 projects are now under construction or have been approved for construction by the States and the Public Health Service.

The total Federal share in the 1,800 projects is 500 million dollars. The States and communities have invested nearly twice that amount.

Despite the fact that these projects will add 88,000 beds to the Nation's health facilities, the construction under the National Hospital Program, plus the very considerable amount of hospital building outside the program, is barely keeping pace with the population rise and obsolescence of hospital facilities. As a result, the need for additional hospitals is still critical.

The Lebanon Community Hospital is typical of the majority of the hospitals completed under the National Hospital Program. It is a one-story structure with two operating rooms for major surgery, plus minor surgery facilities in connection with the emergency room. It has a 16-bed obstetrical department and 18 bassinets. The building is air-conditioned throughout and has a piped-in oxygen system which makes oxygen immediately available in all patient rooms, surgeries, and delivery rooms.

The medical staff includes all six physicians practicing in Lebanon. Through arrangements with larger hospitals in nearby cities, the Lebanon hospital can call upon specialists in pathology, radiology, internal medicine, orthopedies, pediatrics, eye, ear, nose and throat, obstetrics, gynecology, and other fields of medical care.

frontispiece

Final preparations for the opening of the Lebanon Community Hospital are illustrated in these photographs. John Nyland, president of the board of directors, is pointing out the plaque commemorating the founders of the hospital—more than 3,200 citizens of the area who contributed time and money to make this project possible. (Photography through the courtesy of Dalton's Studio, Lebanon, Oreg.)

This new unit of Minnesota's Anoka State Mental Hospital (frontispiece and above) was designed to foster the recovery of mental patients by providing recreational and therapeutic facilities in homelike surroundings. Patient rooms are painted in warm colors; corridors and assembly rooms are walled with light-colored tile. Large wards are eliminated, with no more than four patients assigned to the larger rooms. There are also single and double rooms. The building includes complete facilities for treatment by insulin and electric shock and aquatic therapy.

Each bedroom wing of the new receiving unit has a central nurses' station (frontispiece, upper left), which is located to give complete control over traffic and major functions of the wing. The station juts out into the corridor to give clear vision up and down the hall. Across from the station is the day room for patients, which can be seen in the right background of the picture.

At upper right is a view of the reception area and information desk at the new hospital. Informal furniture groupings, in partitioned areas, provide privacy for family visits. The area has its own rest rooms. Doors lead into the patient examination and admittance areas. The whole atmosphere is bright and cheerful.

A classroom for staff training is located on the second floor of the hospital's rear wing (see lower left). Here new workers receive instructions on care of patients, and refresher courses are held from time to time. A sloping floor toward the platform makes clear vision possible from all parts of the room.

A full-sized swimming pool within the building is available for patient use under supervision of lifeguards trained by the Red Cross. Availability of a pool recognizes the value of aquatic therapy to patients. (Architects: Magney, Tusler & Setter, Minneapolis.)

years ago

in Public Health Reports

THE December 19, 1902, issue of *Public Health Reports* carried a summary report on the international tuberculosis conference held at Berlin, October 22 to October 26, 1902. It was the first conference held by the Central International Committee for the Prevention of Tuberculosis, which had been organized at the international congress on tuberculosis at Naples in 1900. An international congress had also been held in London in 1901.

The report on the 1902 conference, written by the United States representative, Dr. J. M. Eager, of the United States Public Health and Marine-Hospital Service, indicated that the subjects considered included: the position of governments regarding the prevention of tuberculosis; the organization of dispensaries; precautions against the dangers of milk; tuberculosis during infancy; and protection of labor and prevention of tuberculosis. Quoting from the report:

"Dr. Alfred Hillicr, of London, . . . expressed the belief that there are four great measures to which we must look for the prevention and cure of tuberculosis, namely: 1. Penalizing indiscriminate expectoration. 2. Introducing systematic notification of tuberculosis. 3. Insisting on efficient standards of ventilation and light for all factories, public buildings, and private dwellings. 4. The encouragement of the establishment of sanatoria for the two classes of tubercular cases, early curable cases, and advanced cases, and the treatment of phthisical cases in such sanatoria."

Von Baumgarten, of Tübingen, said that "the most direct way to fight tuberculosis was to attack the tubercle bacillus. If success could be attained in destroying this malicious parasite the world would be free from the devastation it produces."

In the discussion of compulsory notification

of tuberculosis, Van Ryn of Brussels, "was of the opinion that, without notification in all countries, it would be impossible effectively to destroy the foci of infection. The objections to notifications are that it is against individual liberty and professional secrecy; that it disturbs the sick; and that as a consequence of notification tubercular patients lose their employment. . . . These objections should be set aside in view of the interests of the general public."

"In an address on the measures taken at Basel to prevent infantile tuberculosis, Prof. F. Egger, of Basel, Switzerland, drew the conclusion that, inasmuch as infantile tuberculosis often assumes manifestations in which treatment is generally unavailing, the most extended prophylaxis is of the greatest importance, and that the treatment of infantile tuberculosis ought to begin, as in adults, with the very first symptoms."

"At the close of the discussion Prof. Robert Koch made a long and interesting statement reaffirming the position he took at the London tuberculosis conference, to the effect that it has not yet been proven that man can be directly infected by the tuberculosis of animals. . . . Professor Koch said that for more than a year past he had gathered official reports of all tuberculous cases treated at German hospitals and coming under the note of the professors of pathology at German universities. Still he had not learned of a single case of primary tuberculosis of the intestines. He admitted that such cases appeared to be more frequent in England than in Germany. . . . He supported his argument by analogy to other infectious diseases, and declared that, in the whole literature of tuberculosis, he knew of no widespread prevalence of tuberculosis traceable to milk or meat."

PUBLIC HEALTH REPORTS

From Yellow Fever to International Health

Public Health Reports had its modest beginning in a one-page "Bulletin" issued on July 13, 1878, by the Supervising Surgeon-General of the Marine-Hospital Service.

Two months earlier, Congress, hoping to fend from American shores the twin scourges of cholera and yellow fever, had passed the first National Quarantine Act. This law required American consuls to file reports on sanitary conditions abroad and on vessels leaving infected foreign ports bound for the United States. From these reports and "other pertinent information" the Surgeon-General was to prepare weekly abstracts for transmission to medical officers of the Marine-Hospital Service, to collectors of customs, and to the State and municipal health authorities in the United States.

The early bulletins, though brief, were grim enough to arrest any reader's attention. Bulletin No. 3 (July 27, 1878) led off with the ominous words, "About the 12th instant, cases of yellow fever began to occur in New Orleans." Thus began the stark record of the great Mississippi Valley epidemic that claimed 20,000 lives. Upstream sped the disease, while authorities

BULLETINS.

No. 1.

OFFICE SURGEON-GENERAL, U. S. M.-H. S.,
Washington, July 13, 1878.

The following information is furnished by the Surgeon-General of the Marine-Hospital Service to State and municipal officers of health, &c., in accordance with the requirements of the National Quarantine act:

Havana, Cuba.—From 20 to 34 deaths from yellow-fever, and more from small-pox, are now occurring weekly in the city of Havana.

Cardenas and Sagua la Grande, Cuba.—Good health in bay and city.

Matanzas, Cuba.—The captain and four of the crew of the bark "Marie Donan" were attacked with yellow-fever on the 3d instant, in the harbor of Matanzas. Only one other case of fever has occurred in the shipping of that port. Sporadic cases are reported in the city, but the disease is of a mild character.

Key West, Fla.—Two cases of yellow-fever have occurred in the harbor of Key West, one on the Norwegian ship "Marie Frederike," and one on the Spanish bark "Doña Talefora." The city is reported healthy.

Two of the British vessels which recently conveyed native Indian troops to Malta, had cholera on board during the passage from India. On one of the vessels nine cases and four deaths, and on the other two deaths, occurred before the vessel passed the Suez canal. The vessels were allowed to pass the canal without detention, though it is customary to send a vessel, on which a single case of cholera has occurred during the voyage, back to Thor, 120 miles, there to remain two weeks or more in quarantine.

JNO. M. WOODWORTH,
Surgeon-General, U. S. M.-H. S.

1881 Reprint of the First Bulletin

tried hopefully but futilely to kill it with carbolic acid—upriver to Vicksburg, to Port Gibson, to Grenada, to Louisville and Cincinnati and as far as Pittsburgh, where a dying steamboatman was carried ashore from the *John D. Porter*, the ill-fated sternwheeler which had left an infected wake for one thousand miles.

The tragic story is tersely told in volume I of the *Bulletins of the Public Health*, and between its laconic lines may be read both terror and heroism. In August, Dr. Booth, in

charge of the Marine-Hospital Service at Vicksburg—where 20 deaths had just been recorded from yellow fever in 24 hours—telegraphed, "I am sick; impossible to procure accurate data." The next *Bulletin* recorded his death.

Yellow fever . . . the Marine-Hospital Service . . . a feeble quarantine act . . . the very terms and conditions of that time recall the sweeping progress in public health since 1878. That progress can be symbolized by the transformation of the *Bulletin*, with its meager abstracts tracing the course of seemingly invincible diseases, to the new *Public Health Reports*, a forum for the thousands of

The New Public Health Reports

The new *Public Health Reports* carries forward a record of service extending from 1878.

The amalgamation, in the present journal, of several other Public Health Service technical periodicals represents, we believe, a strengthening and revitalizing of the *Reports*.

It is, moreover, an attempt to reflect the changing—and broadening—concepts of public health which have been emerging during the past decade.

In 1878, when *Public Health Reports* was founded, its primary function was to carry out the Service's responsibility for compiling and publishing data useful in combating epidemics.

Today, public health responsibility embraces such varied and complex fields as basic research, the problems of the aging, rehabilitation, and hospital construction—in addition to the control of epidemic diseases and the fight against the venereal diseases and tuberculosis.

It is our hope that the new *Public Health Reports* will be a useful and challenging source of information for all who are working in this field. The new monthly journal will focus primarily on public health practice, health service administration, and on research in these fields. It will be concerned largely with those aspects of public health which touch upon the work of the official agencies.

We hope that, as time goes on, it will become a real forum for the exchange of professional ideas and a stimulus toward new and better concepts of public health practice.

To aid in the development of the editorial standards and policies, a Board of Editors has been named. The board is made up of individuals of experience and wisdom in various public health fields. We shall rely heavily upon them and upon our editorial consultants, to whom will fall the task of reviewing manuscripts. I am deeply appreciative of their willingness to aid us in the development of the journal.

The pages of the new *Public Health Reports*, like those of its predecessors, will be open to responsible authors, outside as well as within the Federal service, in the United States as well as abroad.

With this issue—No. 1 of volume 67—*Public Health Reports* turns another page in its long career. Its usefulness, as in the past, will depend upon how well it meets the needs of its readers.

We are relying upon you, as well as upon our Board of Editors and the staff, for contributions and for the kind of constructive criticism which is essential to the growth and development of any publication, new or old.

LEONARD A. SCHEELE, M. D.
Surgeon General

professional and technical workers who are marking up steady advances in a concerted drive to improve the Nation's health. Through the 65 intervening volumes runs the record of the public health movement in the United States—a record of its frustrations and dead ends, of its many victories, of its enduring problems.

Epidemics and Quarantines

The *Bulletins of the Public Health* expired after 46 numbers, leaving a clear field for the short-lived National Board of Health and its quarantine reports. Publication was resumed in 1887, however, when No. 47 came off the press as the *Weekly Abstract of Sanitary Reports*.

The Division of Sanitary Reports and Statistics was responsible for the *Abstract*, and a special officer was detailed to supervise its editing and mailing. Still a bare chronicle of only a few pages, it reached 1,800 readers and was—in its editor's words—"greatly appreciated not only by quarantine officers, but steamship companies, merchants, and the press."

In recording the prevalence of communicable diseases, and little else, the *Abstract* faithfully reflected the public health functions as carried out then by the Marine-Hospital Service. The quarantine powers and duties of the Service, both interstate and foreign, were enlarged by Congressional acts of 1890 and 1893—none too soon, for there was a cholera pandemic in the

Gaylord W. Anderson, M. D., Dr. P. H., is director, School of Public Health, University of Minnesota, and president, American Public Health Association.

Justin M. Andrews, Sc. D., LL. D., a parasitologist of wide teaching and field experience, is in charge of the Communicable Disease Center, Public Health Service.

Halbert L. Dunn, M. D., Ph. D., is a member, WHO Expert Committee on Health Statistics, and chief, National Office of Vital Statistics, Public Health Service.

Martha M. Eliot, M. D., Sc. D., a pioneer in national and international programs for maternal and child health, is Chief, Children's Bureau, Federal Security Agency.

Ruth Freeman, R. N., Ed. D., is associate professor of public health administration, Johns Hopkins University, formerly Administrator of Nursing Services, American Red Cross.

John W. Knutson, D.D.S., Dr. P. H., is known for his work in preventive dentistry and is chief of the Division of Dental Public Health, Public Health Service.

The Board of Editors of Public Health Reports

Dr. McGavran

Edward G. McGavran, M.D., M.P.H., chairman of the board of editors, is dean of the University of North Carolina School of Public Health. He was in the private practice of medicine before becoming associated with the Kellogg Foundation. He has served as a local and State health officer and has taught in the medical schools of Kansas and Washington (St. Louis) universities.

Basil C. MacLean, M. D., M. P. H., director, Strong Memorial Hospital, University of Rochester, is past president, American Hospital Association, and the American College of Hospital Administrators.

Gerard Piel, A. B., formerly science editor of *Life*, is publisher of *Scientific American*.

M. Allen Pond, M. P. H., former Yale professor and wartime director of health and sanitation for the Federal public housing program, is chief, Division of Engineering Resources, Public Health Service.

Fillmore Sanford, Ph. D., a social psychologist and former professor, is executive secretary of the American Psychological Association.

George M. Uhl, M. D., M. S. P. H., health officer, Los Angeles, has been chief and assistant director, bureau of local health service, California Department of Public Health.

Russell M. Wilder, M. D., Ph. D., recently retired from the Mayo Foundation, is director of the National Institute of Arthritis and Metabolic Diseases, Public Health Service.

latter year, and yellow fever struck in Georgia. The Service was strengthened, too, by the creation of the Commissioned Corps in 1889, providing a mobile force of doctors vested with Federal authority.

Medical research had not yet been officially delegated to the Service, but Surgeon J. J. Kinyoun in 1887 opened a one-room bacteriological laboratory in the Staten Island Marine Hospital. There its founder, after the Service in 1890 was ordered to conduct medical examinations for the Immigration Service, first detected the cholera organism among immigrants. The modest research establishment was moved to Washington in 1891, where it became known as the Hygienic Laboratory.

Kinyoun's name looms large in the volumes of the *Abstract*. He wrote its first sizable article—a 31-page essay on the Louisiana State Board of Health and its methods (following which the publication subsided to its customary four pages). His observations on Roux's serum therapy for diphtheria, at the International Congress of Hygiene and Demography in Budapest in 1894, were considered so noteworthy that they were published in the *Abstract* twice within a month.

The *Abstract* became *Public Health Reports* in 1896, but other than the title banner there was little change for several years in either format or content. Epidemics were still the major preoccupation, as public health workers applied their heritage from Pasteur, Koch, and Theobald Smith in detection and control of disease. The *Reports* indicate that an especially close watch was kept throughout the world on plague, smallpox, typhus, yellow fever, and cholera.

Near the turn of the century, yellow fever more than any other disease absorbed the energies of public health personnel. By reason of its official duties, the Marine-Hospital Service was concerned principally with the exacting task of quarantine—a task vastly expanded in magnitude by the Spanish-American War and troop movements to and from yellow fever areas. In the December 22, 1899, issue of *Public Health Reports* appeared the conclusions reached on yellow fever by the Service's investigating commission of medical officers. Their findings, the commission declared, "verify those

of Sanarelli in his discovery of the *Bacillus icteroides*. They further demonstrate that this disease is received into the human system through the respiratory tract." Yet it was Surgeon Henry R. Carter of the Service who first described the extrinsic incubation period of yellow fever, a study which Walter Reed credited with pointing the way to his own epochal discovery of mosquito transmission. The same Carter was to contribute many valuable malaria studies to the *Reports* in the years that followed.

The Broadening Base of Public Health

The first two decades of the new century, culminating in the demands of World War I, saw the modern public health movement in formation. A Congressional act of 1902 changed the Marine-Hospital Service into the United States Public Health and Marine-Hospital Service, and broader responsibilities went with the new title. The Service was given regulatory control over the interstate sale of important biological products. In 1901, Congress had endowed the Service with authority and funds for "the investigation of infectious and contagious diseases and matters pertaining to the public health." From this halfway house, an advance to full-scale field and laboratory investigation was made in 1912, when what now became the Public Health Service was empowered to study not only the diseases of man but also the "conditions influencing the propagation and spread thereof," including sanitation, sewage, and water pollution.

The broadened scope of Service activities soon gave *Public Health Reports* an abundance of important and sometimes dramatic new material for publication. Packed into the fattening volumes, along with statistical reports and tables, were the observations of medical scientists and epidemiologists who were relentlessly whittling down the killing and crippling power of communicable diseases. Here, for example, were Stiles' summaries of his war against hookworm; accounts by Goldberger and Anderson of their investigations into the etiology and prevention of typhus fever; malaria control discussions by Carter and the sanitary engineer Le Prince. Here, in 1906, appeared King's report

on the experimental transmission of Rocky Mountain spotted fever by means of the tick, first in a lengthy series in which Public Health Service researchers pinpointed facts about that disease and immunization against it. Here, too, were recorded the labors of those tireless epidemiologists, Frost and Lumsden, whose work dramatized for countless communities the direct link between environmental sanitation and typhoid.

No chapter in the history of *Public Health Reports* is more fascinating than that which unraveled the mystery of pellagra. In the years before World War I, this disease was recognized as one of the Nation's great public health problems, but its etiology still baffled medical men. In the *Reports* for June 26, 1914, Goldberger, in three and one-half modest pages, advanced the suggestion that pellagra was due to dietary deficiency; and he proceeded to prove his hypothesis in subsequent institutional experiments. His work was not only decisive for the treatment and prevention of a centuries-old disease, it also convinced medical science that bacteriological considerations were not the be-all and end-all of research, and it opened the whole nutritional field which was to prove so fruitful of results.

In the *Reports* of these formative years, too, one may read the signs of a developing Federal-State-local structure for the operation of public health programs. One indication of this cooperative movement was the publication of municipal ordinances, State legislation, and court decisions affecting public health. In 1915 a model State law for morbidity reports was printed.

Along with these new features, statistics remained a vital element of *Public Health Reports*. The reason for these columns of figures was convincingly emphasized as early as 1913, when the weekly report on the prevalence of disease for the first time led off with the now-familiar admonition: "No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring."

Public Health Comes of Age

World War I made strenuous demands on the Public Health Service and local health agencies.

The *Reports* reflected the conviction that physical fitness, for civilians as well as for troops, was a duty owed the Nation. This concern was strikingly shown in the increased number of articles on industrial health. The most important "sanitary problem" facing the United States, however, was the control of venereal disease. Foreshadowing the campaign of the 1930's, the Public Health Service, through its newly created Venereal Disease Division, cooperated with the States in a \$1,000,000 program of prevention and control, one of its aims being the education of the public to "permit the free and frank discussion of this important question without offense to modesty."

The influenza epidemic was the regular front-page topic in 1918-19. The *Reports* noted on October 4, 1918, that the disease was spreading rapidly over the country. Soon the Service was besieged by correspondents offering "sure cures," which ranged from patent medicines to "harmonic vibrations." The epidemic left one useful legacy. It showed "better than volumes of reasoned arguments," said *Public Health Reports*, the necessity for a reserve corps of commissioned public health officers—and such a corps was created by Congressional resolution in 1918.

While the war stimulated public health organization and activity, it also revealed health conditions which were in some respects deplorable. The Service's response to this challenge was a comprehensive program, outlined in *Public Health Reports* for December 5, 1919, embracing industrial control of malaria, tuberculosis and venereal disease, improved morbidity reports, and health education.

The Public Health Service, meanwhile, was developing the role it would play as catalyst and guide for State and local programs. In the *Reports* of the early 1920's, Sydenstricker presented significant findings in the monumental Hagerstown, Md., survey of health and socioeconomic status, a landmark in the study of medical care. And before the close of the decade, studies of local health work began to appear.

Medical research, understandably, continued to command many pages of the *Reports*. As microbiological investigations were carried forward, the names of novel or unusual diseases

made their appearance. Edward Francis labeled tularemia in July 1921. Others inquired into the organisms and the epidemiology of brucellosis. In the late 1930's, Q fever was identified and discussed. In the field of biologics control, investigation of vaccination sequelae began in 1925 and continued for several years, while scarlet fever serum was another topic of the mid-1920's.

A notable program development in the years between the two World Wars was the campaign against venereal disease, given its initial impetus in 1918 and brought to a well-publicized climax in a great drive 20 years later. The pressing nature of the problem was signaled by the appearance of *The Journal of Venereal Disease Information*, which began as a mimeographed abstract in 1920 and later expanded into a printed publication with original articles. The editor was the chief of the Venereal Disease Division, and such chiefs as Thomas Parran were frequently contributors as well. Throughout its 32 volumes, the *Journal* has played a stimulating part in venereal disease control, its articles recording the remarkable achievements in the field.

Maturity and Expansion

Viewed telescopically, the growth of the Public Health Service in the past two decades is startling, almost bewildering. Yet it is well to remember that this growth has not been haphazard but rather a logical development from the past. New programs, new organizational arms, new functions have been added to meet specific health problems or to exploit fresh opportunities. Those problems and opportunities have been discovered in the light of a steadily enlarging concept of public health—a concept that found ultimate expression in the World Health Organization's definition of health as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity."

This developing concept may be discerned in the Social Security Act of 1935, which regularized grants-in-aid to the States, thus providing a solid base for the building of local health services and for such special programs as the care of crippled children, the improvement of

maternal and child health, and tuberculosis control. Four years later the Public Health Service, after 141 years under Treasury supervision, was made a part of the new Federal Security Agency.

Another legislative landmark was the Congressional act of 1937 which authorized a National Cancer Institute and at the same time empowered the Surgeon General to provide research grants and fellowships for the study of cancer. Thus the pattern was set for the present broad research grants program; and simultaneously a beginning was made along lines which eventually brought the establishment, at Bethesda, Md., of the seven research groups of the National Institutes of Health.

Even in a brief survey, one further law deserves mention—the Hospital Survey and Construction Act of 1946, which gave the Public Health Service responsibility for a \$75,000,000-a-year program of hospital construction carried out through grants to the States.

Map of the District infected by Plague. The lines a-a. represent the military Cordon drawn around the infected villages; and b-b. the protective Cordon maintained around Zarigin, an important Commercial point, and terminus of the Russian Rail-road system. The village of Wetjankaja was the original and principal centre of infection.

One of the First Illustrations in the Forerunner of Public Health Reports

Another and a tragically different stimulus to expansion was World War II, in which the contributions of the Public Health Service ranged from an intensified venereal disease control program to the recruitment of a Cadet Nurse Corps. On the industrial front, the Service developed methods which reduced TNT poisoning. Fighting men benefited by new or improved vaccines for typhus, yellow fever, and plague, by antimalarial drugs, by the Service's studies on the effects of high-altitude flying, and by the mass processing of blood to plasma in the Biologics Control Laboratory.

Among the major postwar developments was the establishment of the Environmental Health Center in Cincinnati and of the Communicable Disease Center in Atlanta, each a national headquarters for intelligence, planning, and research in its field. The Communicable Disease Center grew out of the program launched in 1942 for Malaria Control in War Areas. The attack on malaria was chronicled by its own publication, the *MCWA Field Bulletin*, which gave way in 1946 to the *CDC Bulletin*. This periodical has featured articles by scientists in the forefront of the drive against communicable diseases, as well as reports of operational and research programs in the Communicable Disease Center.

In much the same way, the postwar tuberculosis control program and the creation of the Tuberculosis Control Division in the Service gave rise to its own publication, the Tuberculo-

sis Control Issue of *Public Health Reports*. This special monthly issue began in 1945, 2 years after editorial direction of the *Reports* was assigned to the chief of the Division of Public Health Methods in the Office of the Surgeon General. Contributions, from domestic and foreign sources, have been notable stimuli to a renewed attack on an old killer.

The amalgamation of these three technical periodicals of the Public Health Service with the weekly *Reports* to form a "new" monthly *Public Health Reports* reflects a growing realization of the practical interdependence of public health activities. The merger is a natural development, moreover, at a time when the great problems and even greater opportunities in public health require an integrated and flexible Public Health Service. Such terms as ACTH and cortisone, arctic health and world health, fluoridation, biological warfare, and radiological protection are reminders of how wide-ranging and adaptable the Public Health Service must be.

The Public Health Service has come a long way since that day in 1878 when the dying Dr. Booth sent his pathetic telegram, "I am sick; impossible to procure accurate data." Yet Booth is part of an enduring tradition, for the assembling and dissemination of data is the very basis of effective public health work. That tradition the new *Public Health Reports* will keep alive.

Scheduled For Early Publication

Aging: Its Implications for Public Health.—An over-view of the problem, by Clark Tibbitts, plus briefs of more than two dozen papers presented at the Second International Gerontological Congress.

Definitions and Functions: The Health Department's Dilemma.—An examination of the changing role and expanding responsibilities of the modern public health department, by Joseph W. Mountin.

Research for Improved Nursing Practice.—A discussion of current needs and developments in a field that requires increased attention, by Lucile Petry, Margaret Arnstein, and Pearl McIver.

50th Conference of State and Territorial Health Officers.—Shortened texts and reports of the major papers presented before the health, hospital planning and construction, and mental health authorities of the Nation.

Research in the Epidemiology of Mental Illness.—A review of current projects and emerging needs, by Robert H. Felix and Morton Kramer.

The CMP and the Public's Health

By W. E. GILBERTSON, B. S. E. E., M. P. H.

How will the Controlled Materials Plan affect health and medical care facilities?

What's ahead in 1952?

What is the expected level of hospital and health facility construction?

Will there be a sufficiency of health and medical equipment and supplies?

Can we maintain our standards of medical care?

Defense Mobilization

Immediately following Korea, our Nation decided to step military defenses up to the brink of constant preparedness—a policy designed to protect the United States from the imminence of aggression. The Congress passed the Defense Production Act on September 8, 1950, giving the President emergency powers to allocate materials and facilities “in such manner, upon such conditions, and to such extent” as he deemed “necessary and appropriate to promote the national defense.” The language of the act was simple but the decisions to follow were to be the difficult ones of gearing for war—and ones of far-reaching significance to public health.

Public Health and the Defense Program

Late in 1950, the Federal Security Agency was designated a “claimant agency” with jurisdiction over health, education, welfare, recreation, and sanitation programs (with the exception of water supply and sewage disposal). The Federal Security Agency then delegated to

Mr. Gilbertson, who is chief of the Division of Civilian Health Requirements, Office of the Surgeon General, was formerly executive officer for the Public Health Service's Communicable Disease Center in Atlanta.

New hospital construction means large quantities of controlled materials—Steel, Copper, Aluminum.

the Public Health Service responsibility for the claimant program of estimating and presenting to appropriate authorities the requirements of the health and medical segment of the national economy. This is the first time the Public Health Service has been called on to perform such a function. During World War II all claimant responsibilities were confined to the War Production Board.

Control of production for defense is divided between the over-all planning organization of the Defense Production Administration and its sister operating agency, the National Production Authority. Twenty government agencies, in addition to the Federal Security Agency, and 35 industry divisions in the National Production Authority represent particular segments of the national economy as claimants.

The claimant agency program for health combines a double responsibility: first, the authorization for construction of all civilian hospitals and health facilities applying under the Controlled Materials Plan with corollary allotments of controlled materials by calendar quarters for each project approved; and second, analysis of the domestic distribution of health and medical supplies and equipment to the

civilian population. The Public Health Service health facility program does not include construction of military or Veterans Administration hospitals.

What Is The Controlled Materials Plan?

The Controlled Materials Plan—CMP—is based on World War II experience, and CMP can best be described as the theory of balancing supply and demand within the available resources of steel, copper, and aluminum.

CMP places production responsibility on a prime contractor in terms of end products to be produced at a given time, in a given quantity. In health facility construction, for example, the prime contractor would be the principal contractor for a hospital, or in the manufacture of health and medical equipment and supplies, he might be the manufacturer of X-ray machines. The prime contractor passes on authorized construction (or production) schedules to the subcontractors supporting him. Allotment of controlled materials is by weight, in such forms as they are produced at the mills—sheets, plates, tubes, bars, angles, and others. There are certain civilian-type end products not lending themselves to a vertical type of handling which are allotted by dollar value through the issuance of priority ratings for their purchase. In hospital and health facility construction, examples of these products would be lighting fixtures, metal sash and doors, and mechanical equipment.

Civilian Health Requirements

To discharge public health claimant responsibilities, the Division of Civilian Health Requirements was created in the Public Health Service and staffed with public health personnel experienced in World War II procurement and hospital construction.

One of the initial steps taken by the new Public Health Service division before CMP was to prepare long-range estimates of expected consumption or use for more than 1,100 products and for the quantities of materials urgently needed for new and under-way construction. Expansion of productive capacity was urged wherever study revealed that critical shortages

of health and medical supplies and equipment might be encountered.

Under the Controlled Materials Plan, the Division of Civilian Health Requirements receives from the Defense Production Administration quarterly allocations of controlled materials for the construction of health facilities, including hospitals, health research activities, health centers, group practice clinics, convalescent homes providing medical care, nurses' residences, and refuse disposal systems for public use. The division allots metals from its quarterly CMP bank of materials by issuing authorizations permitting eligible projects to draw on approved amounts of materials. Issuance of allotments to individual projects follows careful screening for essentiality.

Today, all uses of critical materials demand careful examination. Why is construction of this hospital required? Can it be deferred for 6 months? For a year? Have financing arrangements been completed? Can the project be staffed upon its completion? Are there enough doctors available? Nurses? Where is it located? What is its relationship to the defense effort?

The answers to these and similar questions provide a basis for examination of proposals for health-type construction, and simply mean that new hospitals not urgently needed may have to be deferred. All health facility projects are ranked according to essentiality. Under the Public Health Service plan for screening projects, proposals for hospital construction receive first consideration if the new facility will maintain or add beds in critical defense areas or in defense-impacted communities where the need is urgent. Second priority is given to localities having no hospitals within reasonable traveling distance. Then there are areas with descending degrees of hospital bed shortages. Similar criteria of essentiality are used for classifying proposals for other types of health facilities.

CMP and Health Facilities

To consider how the operation of CMP will affect our standards of medical care and how it will affect hospitals and other health facilities, varying factors must be weighed carefully:

1. A comparison of the current rate of new construction with the recent past. 2. A comparison of estimated metals requirements for public health construction with the metals allocations received under CMP. 3. The relationship of the current rate of construction to unsatisfied needs. 4. Future trends, using the limited experience of the first two quarters of operation under the Controlled Materials Plan as the basis for prognostication.

Accurate figures on the completion rate of new hospital beds in the decade from 1930 through 1939 have been difficult to obtain (see chart). The best estimates available show that the yearly average provided an additional capacity of approximately 11,700 beds. Construction dropped almost to a standstill during the depression years. And hospital construction especially, during the mid-1930's, was at a low ebb. Early war years saw some emergency building but not enough to dent the long-accumulated deficit.

Following World War II, materials again began to flow into construction. With the enactment of Public Law 725 (79th Cong., 2d sess.), providing Federal aid for hospital survey and construction on a matching-funds basis (the Hill-Burton program), impetus was given to hospital and health center construction. During the period 1947 through 1950, hospital bed capacity jumped to an average increase of 32,800 beds per year.

By January 1951, the total acceptable hospital bed capacity throughout the States and Territories exceeded a million beds. The rate of construction for the year 1950 was about 57,000 new beds, of which an estimated 12,000 are considered to be for attrition due to fire, obsolescence, and other causes, leaving a remainder or net gain of 45,000. But the bed deficiency still was 873,000 and only 54 percent of the Nation's needs were being met.

For public health centers and such auxiliary health facilities as laboratories and clinics, present program plans of the States call for an increase to two and one-half times the number of existing facilities. Ultimately, needs will require an increase of 8 to 10 times the number we now have.

Because full CMP has been in operation for such a short time, data available within the Di-

vision of Civilian Health Requirements covers only 6 months of actual experience in estimating and allocating controlled materials for health facility construction. Current construction of health facilities under CMP can be analyzed, therefore, only in terms of materials requested, materials received, and projects processed by the division since the commencement of CMP—that is, the third and fourth quarters of 1951 and the first quarter of 1952.

The table shows the record of materials requirements submitted by the Public Health Service, allocations received, and percentages of the relationship between allocations and estimated requirements for each quarter.

PHS requirements and CMP allocations for health facility construction by calendar quarter

	Carbon and stainless steel (tons)	Copper wire and brass mill products (000 lb.)	Aluminum (000 lb.)
Third quarter 1951:			
Requested.....	102, 852	7, 256	1, 059
Received.....	75, 475	4, 514	550
Percent of require- ments received....	73	62	52
Fourth quarter 1951:			
Requested.....	101, 206	4, 375	1, 049
Received.....	81, 529	2, 640	500
Percent of require- ments received....	81	60	48
First quarter 1952:			
Requested.....	99, 305	3, 699	619
Received.....	71, 285	2, 733	400
Percent of require- ments received....	72	74	65

More than 2,000 construction project proposals have been processed within the Division of Civilian Health Requirements since the beginning of CMP. Of this number, approximately 60 percent represents hospital and health facility construction under way as of July 7, 1951, and 40 percent represents proposed new construction "starts."

To date, all under-way projects have been approved with the exception of a few large construction jobs in which the metals requirements exceeded the allotment capacity of the division. A few—87—fourth-quarter 1951 applications for new starts were deferred and most of the new starts—145—for the first quarter of 1952 were deferred. In the first quarter of 1952, approximately 90 percent of the metals allotments were made for projects under way.

These figures may perhaps be better expressed in the tabulation below showing the number of new hospital construction projects processed in the division and the number of beds to be added to the Nation's total upon completion of the proposed projects. Excluded are projects for rewiring, boiler repair, reroofing, or any similar construction jobs not adding to the bed capacity of a facility. The figures given for the first 3 months of 1952 are by their nature estimates, and as such represent proposed hospital projects approved on the basis of the controlled materials available for allotment as of November 30, 1951.

Construction of hospital beds authorized under the Controlled Materials Plan

Period of authorization issuance	Number of new projects approved	Estimated additional beds
1951 (July-Aug.-Sept.)-----	190	14, 250
1951 (Oct.-Nov.-Dec.)-----	150	8, 600
1952 (Jan.-Feb.-Mar.)-----	100	4, 000

Assuming that in the second quarter of 1952, the commencement of new hospitals will be on a par with 1952's first quarter, we can estimate the expected total of additional hospital beds to be provided by new construction projects starting during the 12-month period beginning July 1951 and ending June 1952, as approximately 30,850. If this expected total is compared with the calendar year 1950, it represents 54 percent of the total bed capacity attained during 1950. For the same 12-month period, it is estimated that 60 new health center projects will be started, representing 4 percent of the existing programed need.

It is apparent that the rate of hospital construction is not in keeping with needs. It is evident that although we face a shortage of health facilities, the situation cannot be corrected at the present rate of programing hospital and health facility construction within the quarterly metals quotas assigned under CMP. But it should be stressed that without CMP, hospital contractors and builders would be forced to compete on the open market, thus opening the way to prohibitive costs and unfair and discriminatory practices and without any assurance of seeing a construction project through to its final completion and operation.

The Health Program and the NPA

The Public Health Service believes that production of sufficient health and medical supplies and equipment must be maintained at a consistently rising level to stock new hospitals and other health-connected buildings when their construction phase is complete, and to provide for military, civil defense, and normal civilian health requirements. Production must be maintained also, insofar as possible, to provide for repair, maintenance, and operating supplies and equipment in health facilities.

There are three industry divisions within the National Production Authority whose allocation programs of controlled materials are of major importance to public health needs. Two of these three divisions are closely allied to the Public Health Service claimant program because they request and allocate the metals necessary to manufacture hospital supplies and equipment. The Consumers Durable Goods Division and the Scientific and Technical Equipment Division share responsibility for the allocations to the manufacturers of medical equipment and supply items.

Municipal water supply and sewer construction programs are not included in the Public Health Service area of claimant activities but come within the jurisdiction of the Water Resources Division, the third health-allied NPA industry division. It is responsible for allocating controlled materials to both domestic and industrial water and sewage projects, except operations for navigation, flood control, reclamation and irrigation, hydroelectric generation of power, recreation, and fish and wildlife.

Courtesy S. Blickman, Inc., Weehawken, N. J.

New equipment—such as this—is needed for hospitals under construction and to replace obsolescent equipment.

G. E. Arnold, director of the Water Resources Division, has stated the public health aspect of this construction: "Water and sewage facilities are essential to maintenance of the public health. Every effort will be made to maintain essential public health facilities, but because of the critical shortage of materials many desirable, if not essential, water and sewage construction jobs will have to be deferred. It is urged that only those jobs that can be classed as strictly essential to public health be constructed at this time."

Most medical equipment and supply items are manufactured from metals allotments approved by the Scientific and Technical Equipment Division of NPA. Among other categories of products, the division receives allocations for the distribution of controlled materials required for the manufacture of optical instruments and ophthalmic goods, laboratory, dental, surgical, medical and scientific instruments, and surgical and orthopedic appliances and supplies. Like the Public Health Service, it operates under a policy of priority consideration in distributing quarterly allotments. Essentiality is divided into three preference groups:

1. The direct requirements for armament and defense purposes—precision devices and instru-

ments for military or atomic energy programs are examples.

2. Other essential (and immediately necessary) requirements—such as any of the medical and surgical types of equipment required for civilian health use.

3. Requirements which can, if necessary, be substantially reduced as facilities are converted to the production of materials for defense—for instance, clocks or watches.

In keeping with the policy of the NPA, the Scientific and Technical Equipment Division, according to Howard A. Pringle, its director, "is exerting every effort to provide sufficient medical equipment and instruments for both military and essential civilian needs. Some substitution of less critical for more critical materials may be necessary whenever the functional qualities of the product will not be impaired by such substitution. There is every indication that there will be adequate supplies in all essential categories for all needs in this field."

Analysis shows that the estimated metals requirements made by the Scientific and Technical Equipment Division for the first quarter of 1952 were granted at the level of between 75 to 95 percent of need. Actual weight allotments of metals for this quarter compare favorably with the first two operating quarters under CMP. Few problems have developed in programming medical supplies, and when this has happened, the division has responded by reducing some of the metals allotments in the lowest priority group.

In line with NPA policy, the Consumers Durable Goods Division classifies as "preferred products" items possessing military, public health, medical, or civil defense application. "We consider health and medical supplies as 'preferred products' and give them top priority along with many military items," the division's director, Harry J. Holbrook, has stated, adding, "hospital kitchen equipment, for example, is vitally important to the successful operation of our medical care institutions. We will do our best to see that sufficient materials are channeled into these essential products to care for real needs." First-quarter 1952 allocations for preferred products averaged about 65 percent of

the consumption of the base period, January to June 1950.

The next priority grouping covers the bulk of consumer items used in homes and businesses—refrigerators, domestic stoves, and office desks and supplies. Naturally, normal consumer requirements comprise a significant proportion of the national metal supply. First-quarter 1952 allocations were made at levels of 50, 35, and 35 percent of the base-period consumption of steel, copper, and aluminum, respectively.

The lowest priority class contains a variety of least essential items for which known substitutions can be made for metals, or which can be entirely eliminated. Jewelry, advertising signs, venetian blinds, fireplace equipment are types of products found in this category in which allotments made for copper and aluminum were at 10 and 20 percent of the base period and 50 percent (or more, under some conditions) for steel.

Production Policy for Defense

Growing civilian needs and increasing military and civil defense purchases are the most important factors behind the increase in consumption of medical supplies. Population growth, our improved economic status generally, and the resultant demand for medical care have, in recent years, increased civilian consumption. It is expected that for the military procurement program there will have been expended 425 millions of dollars on medical supplies alone during the 12-month period ending June 1952. Compare this with the fiscal year ending June 1950, just preceding Korea, when 35 millions of dollars was the extent of the same procurement. Civil defense purchasing entered the medical supply field in the year just past, and this year it is expected that civil defense purchases will range between 75 and 85 millions of Federal and State funds.

In a sense, part of the problem of allocating metals is impossible to solve at this stage. The amount of controlled materials available is not sufficient "to keep everybody happy." Total

stated requirements of estimated national needs for the first quarter of 1952 amount to 65, 61, and 51 percent more than the available supply of steel, copper, and aluminum.

Industrial, institutional, and farm scrap drives to recover usable metals are being promoted through the press, trade associations, chambers of commerce, and government agencies. A long-range program to aid industry in expanding its production of critical metals is now in process. Since it takes steel to produce steel, it can be expected that a significant portion of the controlled materials now available will be devoted to increasing industry's production capacity.

The general policy under which CMP now operates requires that all uses of critical materials must receive some consideration whatever the level of essentiality may be. Defense Mobilizer Charles E. Wilson clarified the policy in his report surveying the first 3 months of CMP progress: "Keeping in mind that defense mobilization is a long-range program, our aim is to build our military productive capacity while maintaining at least a minimum operation of civilian industry—rather than undertake wholesale conversion of civilian plants as we would be forced to do under conditions of full mobilization."

The current pattern of allotting controlled materials permits allotments for "least essential" products at a lower percentage, it is true, of their stated requirements than approved for the more preferred product classes, but manufacturers of these products may hope to continue "in business" until a normal product conversion to essential categories can be accomplished. The first 6 months of controlling materials and production was a period of transition. We can expect that the early months of 1952 will be a lengthening of the transitional period. At the same time, we may expect that, with no change in the international atmosphere, construction of hospitals and health facilities and the manufacture of medical supplies and equipment for civilian use will continue because they are indispensable health programs—but they will continue at a lower rate.

Susceptibility of *Anopheles Quadrimaculatus* To Korean Vivax Malaria

By MARTIN D. YOUNG, Sc. D., and ROBERT W. BURGESS, Ph. D.

During the summer of 1951, it became increasingly evident that many of the troops returning to this country from Korea were relapsing with malaria. In a personal communication dated September 15, 1951, Dr. Tom Whayne, of the Division of Preventive Medicine, Department of the Army, stated that during the 14-month period ended August 31, 1951, 6,642 cases of malaria had been reported in 100,618 individuals returned from the Far East Command, a reported incidence of 6.6 percent. The case histories indicated that the malaria was acquired in Korea.

The possibility of foreign malarias becoming established in this country is of vital concern to all health officials, especially at the present time, because of the current low incidence of indigenous malaria and the hopeful and progressive signs of its eventual eradication.

The object of the present study was to test the ability of the most important native malaria vector, *Anopheles quadrimaculatus*, to become infected with and to transmit the malaria relapsing in returned troops.

Methods

Veterans with clinical symptoms and positive blood smears volunteered for the tests. Only

Dr. Young and Dr. Burgess are with the laboratory of tropical diseases of the National Microbiological Institute, National Institutes of Health, in Columbia, S. C. Their paper was presented at the joint meeting of the National Malaria Society, the American Society of Tropical Medicine, and the American Society of Parasitologists November 17, 1951, in Chicago.

those soldiers whose histories indicated that their malaria had been acquired in Korea were used in the experiment. Fifty-three patients were tested.

Table 1. Malaria infections in *A. quadrimaculatus* mosquitoes infected by biting 35 soldiers relapsing with vivax malaria acquired in Korea

Patient No.	Mosquitoes fed upon patients			Oocyst per infected gut (average)
	Number dissected	Number infected	Percent infected

A. quadrimaculatus, Q-1 strain, were allowed to obtain a single blood meal by biting the soldiers before treatment for malaria was started. The insects were then incubated at $76^{\circ}\text{F} \pm 2^{\circ}$, at a relatively high humidity. Dissections were begun 6 to 8 days after the blood meal, to determine if malarial oocysts were present on the gut. If a group of mosquitoes proved to be infected, either moderately or heavily, some of the mosquitoes were incubated several days longer and then dissected to determine if sporozoites were present in the glands.

At least 10 mosquitoes from each group were dissected; the usual minimum number was 20.

Observations

Plasmodium vivax was the organism found in all the infections observed. Of the 53 patients tested, 35 (66 percent) were infective to *A. quadrimaculatus* (table 1); 18 lots of mosquitoes (1,192 individuals) showed no infection after biting the remainder of the patients in the tested group.

Some of the mosquitoes showed extremely heavy infections; those fed upon patient K-24 averaged 267 oocysts per gut. The infection in the mosquitoes followed a fairly normal pattern and completed the cycle, with sporozoites demonstrated in the salivary glands. The infected mosquitoes transmitted the malaria to persons with neurosyphilis when the latter were exposed to their bites.

Discussion

Malarial infections in the troops tested were undoubtedly delayed primary attacks or relapses, probably the latter. The histories indicated that the relapsing patients had been in Korea during the malaria season of 1950 or 1951, usually the former year. A single tablet containing 0.5 gm. chloroquine diphosphate (equivalent to 0.3 gm. of the base) had been given weekly as a suppressive treatment (1). Sometimes this weekly dose was missed because of the exigencies of battle. As a rule, the first frank attack of malaria did not occur until suppressive drugs were discontinued, either during or after the soldier's return to the continental United States.

The military personnel tested by us were bitten by mosquitoes within a few hours after a definite diagnosis of malaria was made. Two-thirds of them were infective to mosquitoes, about one-half of them highly so. Past experience (2, 3) has shown that malarious patients may be infective to mosquitoes for several days before the first frank malarial paroxysm or during asymptomatic periods. Therefore, it is likely that some of these soldiers were capable of infecting mosquitoes before a diagnosis of malaria was made.

It is evident from our results that the malaria in returning troops is infective to a mosquito vector. The pattern of the relapses so far is such that most of them occur during the malaria transmission season in the United States. As a result, the potential exists for the establishing of foci of malaria. On the other hand, because of the present awareness of this danger by local, State, and Federal health authorities and by the officials of the armed services, who are employing control measures in the vicinity of hospitals, the danger of establishment and spread of this foreign malaria is greatly lessened. The weakest link in this chain of protection is the individual veteran who has malaria. The Korean veteran with whom we have had contact does not seem to be as well indoctrinated as the veteran of World War II in the possibility that he may develop or relapse with malaria. When the World War II veteran relapsed, he would often suggest malaria to the physician as the cause of illness, but, in general, the Korean veteran does not appear to have this awareness of malaria. However, the Army recently has begun to inform veterans returning from Korea that they may develop malaria. These troops are given a prepared statement to that effect, to be presented to a doctor if malaria symptoms occur.

The relapse pattern suggests that the Korean *vivax* malaria differs from the South Pacific malaria which was imported following World War II. At present, studies are under way to determine certain biological phenomena of the Korean malaria, such as characteristics of the primary infection, natural and acquired immunity, and the comparative infectiousness of Korean malaria to various vectors.

Summary and Conclusions

1. Fifty-three returned veterans with *Plasmodium vivax* infections, apparently of Korean origin, were bitten by *Anopheles quadrimaculatus* mosquitoes. In 35 of these cases the mosquitoes developed malaria.

2. The *A. quadrimaculatus* mosquitoes appeared to be highly susceptible to the malaria tested; in favorable cases, 100 percent of the insects were infected; and the infections developed to maturity. Transmission to susceptible persons by mosquito bites was successful.

3. The potential for the establishment of foreign malarias is present. The weakest link in the chain of control is the apparent lack of appreciation of the danger of relapse with malaria on the part of the infected veteran. With the present awareness of the danger by health authorities and officials of the armed services, the

chances of this malaria becoming established are greatly lessened.

ACKNOWLEDGMENT

We are indebted to Col. Kermit H. Gates, MOC, and the staff of the Fort Jackson, S. C., hospital for their cooperation in these studies. Also we wish to thank Dr. Tom Whayne, chief of the Division of Preventive Medicine, Department of the Army, for information concerning the incidence of malaria in returned troops.

Radiological Health Training Courses

Training courses in radiological health will be given by the Public Health Service at its Environmental Health Center in Cincinnati, Ohio, beginning January 21, 1952. The program has been instituted to aid professional workers in the related fields of radiation to achieve a broader understanding of its hazards and problems.

Candidates should have a degree in medicine, engineering, physical science, or biological science, and experience in work relating to public health.

Basic courses are scheduled for January 21 to February 1, March 10 to 21, and April 21 to May 2, 1952.

Intermediate courses are scheduled for February 4 to 15, and May 5 to 16, 1952.

The subjects outlined for the basic course are the theory of radiation and detection instruments, use and maintenance of instruments for measuring radiation, the detrimental effects of radiation, methods used for protection and shielding against radiation, and the recommended permissible dosage.

Intermediate courses for those having completed the equivalent of the basic curriculum provide 2 weeks of training in the operation, maintenance, and repair of radiation detection devices used in the monitoring of personnel and in the monitoring of water, food, and other samples.

Additional information concerning the curriculum and application procedure may be obtained from the Chief, Radiological Health Training Section, Environmental Health Center, 1014 Broadway, Cincinnati 2, Ohio.

Venereal Disease Control Program In Transition

By THEODORE J. BAUER, M. D.

Substantial gains continue to be made in reducing the incidence of syphilis in the United States.

Total syphilis morbidity reached an all-time low of 214,000 cases in fiscal year 1951. This is a reduction of nearly two-thirds since 1943.

Admissions to mental institutions for psychoses due to syphilis were reduced by one-half in the decade 1939 to 1949.

Mortality due to syphilis in the period 1937 to 1950 also was reduced by one-half.

Our balance sheet, however, is not all credits. Some items still are entered in red ink: gonorrhea rates continue high—about 280,000 reported cases per year; there is evidence that chancroid is on the upgrade in one or two areas.

But, of considerably more significance, there is evidence that where control activity has been relaxed in this country since World War II, venereal disease rates have remained high. Although these instances are few, they are ominous.

If never has been the policy of the Division of Venereal Disease to cry "wolf!" We do not consider that venereal disease will get out of hand again. On the contrary, we are determined that our control efforts will force a continued decline in morbidity and mortality.

Dr. Bauer is chief of the Division of Venereal Disease, Public Health Service. He presented this paper at the Venereal Disease Control Seminar held in New Orleans, La., October 3-4, 1951.

There is, however, no foreseeable terminus to venereal disease control short of extinction of the disease organisms in this country and abroad. Generally, communicable disease control is based on at least four fundamental operations:

1. Immunization of the population.
2. Isolation of the host.
3. Elimination of the intermediate host.
4. Destruction of the organism.

Only Control Element

In venereal disease control, we have no agent for immunizing the population. If one were available, its use would be questioned and its application costly.

We cannot isolate the host without branding him as a moral delinquent—which (by any standards) frequently is not the case; without finding him—which even now we can do only in about one-half of the cases; and without an infallible diagnostic procedure—which we do not have.

We cannot eliminate the intermediate host, since there is none.

We can destroy the organism, but only after it has announced its presence in the host—an announcement which may or may not be heeded if noted, and an announcement which frequently is never noted.

Thus, our entire control effort is balanced precariously on only one of the four elements in the classic foundation of communicable disease control. With the single exception of treatment, the odds in this struggle are with the spirochete and the gonococcus. Especially is

this true during such a tense period of preparation of our defenses for the potentialities of aggression as the present.

Program Change Indicated

If we are to maintain the gains we have made to date and continue to extend them in the future, certain shifts in program policy and operation seem clearly indicated.

Our program must be shaped to current changes in the character and location of the problem, the movements of the population, and trends in therapy. One device for this orientation of program to problems in venereal disease control is increased project assistance.

These projects make possible the immediate application of Federal, State, and local resources to specific venereal disease control problems within the States and communities, wherever such problems arise and for as long as they exist. Federal project assistance supplements State and local resources and other types of Federal aid which support more permanent activities and do not permit the operational flexibility of project assistance.

Because of the scattered and shifting foci of infection, State and local health departments may not be expected to carry the burden of control and programing alone. These foci often are located in areas extending across State and local boundaries and can be detected only from a searching analysis of data collected throughout the Nation. Activities deriving from these analyses require joint planning and programing by Federal, State, and local agencies, including the military.

Large-scale case-finding projects, as we now know them, could not have been initiated without the rapid treatment center. Their continuation after the centers were established served to exploit to the fullest the service potential of the rapid treatment center projects. So successful was this exploitation that the rapid treatment centers have, over the years, treated hundreds of thousands of infected individuals.

Treatment Methods Changing

During this period, treatment practice has progressed to such a degree that in many areas

continued support of the rapid treatment center cannot be considered economically sound public health administration. For the most part, particularly in urban areas, treatment now may be administered more practically and efficiently in out-patient rather than in in-patient facilities. We are currently in transition between these two methods of treatment, and our control methods must be directed accordingly. I am convinced that the exploration, development, and administration of the most effective transition with the least loss in adequate control will result from project activities. These alone permit the flexibility of plan and operation required in the present transition period.

Interviewing Problem Created

To illustrate the difficulties that are involved in the transition from in-patient to out-patient therapy, consider the problem in interviewing: At the present time, and with notable exceptions, our evaluation reports indicate that the bulk of successful contact investigation is carried on by the States, where the majority of patients go to the rapid treatment centers for therapy. Here they are interviewed, educated, and reinterviewed, with resultant high contact indices and with sufficient care to permit location and examination of their contacts. Transition to the use of out-patient facilities means that interviewing skill no longer can be concentrated in one or a few rapid treatment centers, but must in some manner be made available to both out-patient clinics and private physicians. We may not be able to continue the process, basic to control, of finding and examining contacts of infectious cases when these cases appear in the out-patient clinic and the private physician's office.

In parts of the country which have never had as complete a rapid treatment center system as the South, much work has been done to meet the problem of providing interviewing skill in local areas. Such experience may be of considerable help to us. For example, the North Dakota State Department of Health is planning to use the State highway commission's broadcasting facilities, so that the venereal disease control office at the State capital can keep in constant communication with its two investi-

gators. These investigators work throughout the State in following contacts, suspects, premarital and prenatal cases, and all other persons who, by one means or another, can be benefited by epidemiological aids. Code use of such facilities can preserve the confidentiality of reports.

A group of Middle Western States is developing a program of mutual assistance which will permit interviewer-investigators from border areas and military stations to cross city, county, and State boundaries to carry out their investigations. This will be especially helpful when patients are unable to give the name and address of sex partners but would be willing to accompany an investigator in an effort to locate the contacts.

Expanded use of the telephone and telegraph facilities of the Nation increasingly will be called for as the incidence of venereal disease decreases and the work of venereal disease workers is extended to cover larger geographic areas and an increased number of admitting facilities.

Another program being undertaken by the Division of Venereal Disease is working with medical schools that offer postgraduate training to general practitioners and to specialists. We will arrange for physicians qualified in the field of venereal disease to speak at these postgraduate courses. They can present the latest information on diagnosis, treatment, and the need for providing an opportunity to interview the venereal disease patient to find his contacts. The general practitioners will be informed that this latter service will be made available by the State health authorities to the private physician, whether or not he is officially participating in the State's diagnosis and treatment plan.

It is my belief that interviewing can be improved everywhere. Part of this improvement should come from more effective methods applied in the patient interview. Part of it should derive from an extension of the time period in the patient's life covered by the interview. Still another part should derive from the careful interview of late syphilis and gonorrhea patients whom we have, for the most part, ignored in the past.

Finally, consideration and further study

might be made of the possibility of including in our case-finding activities the investigation of the patients' friends, associates, and accomplices who broadly can be indicated under the term "suspects."

Interviewing and contact tracing require uncommon talents. Not everyone in public health work nor even everyone in venereal disease control work has these talents. Careful training is helpful. At present, we are working on a procedure combining training with self-selection. Mobile sound-monitoring equipment is being assigned to a number of larger local health departments in the country. With this equipment, interviewers may listen to each other in actual interview situations. Those who show exceptional skill and who demonstrate interest in this type of work will be encouraged by health officials in many areas to assume exclusive responsibility for interview-investigation activities.

Interviewing, however, is not the only problem raised by the discontinuance of some rapid treatment centers. Another factor inherent in the transition from in-patient to out-patient treatment applies to those who administer treatment. Physicians, local clinics, and health departments must be re-alerted to look for syphilis and to the best and most modern methods of diagnosis and proper treatment. We are now in the fortunate situation of being able to recruit and assign some of the junior medical members of the Public Health Service's Commissioned Corps to State health departments needing assistance during the defense mobilization period. These officers will be especially helpful in States where the transition from in-patient to out-patient is under way.

Attention has been directed to the problems we are facing and the adjustments we must make to meet them. Two more problems in this field deserve brief comment. One of them pertains to mass blood-testing surveys.

Mass Blood Testing Analyzed

Current analysis of mass blood-testing programs in high-prevalence areas indicates that:

1. They do not find all of the syphilis present in the population.

2. Unless the mass-testing activities are fortified with diligent investigation, they do not prevent the redevelopment of foci of infection.

Reports received from a survey in a large city in 1950 indicate a higher percentage of positive serologic results among a sampling of persons who did not apply for diagnosis during the survey than among those who did. Similarly, figures on syphilis morbidity subsequent to the blood-testing programs carried on in several areas clearly indicate that, in spite of the large numbers of persons tested during the programs, morbidity rates remain relatively high unless proper venereal disease control activity follows the survey.

It would seem, therefore, that mass blood-testing activities should be encouraged only among high-prevalence groups which are carefully pinpointed through the analysis of previous patient admissions, contacts, and suspects. These activities, in themselves, never should be considered to provide complete venereal disease control service.

Gonorrhea Control Important

The other problem relates to need of renewed activity in the mass control of gonorrhea. At the present time the Armed Forces report at least seven cases of gonorrhea for each case of primary or secondary syphilis. Though the treatment of gonorrhea is not a difficult problem in either civilian or military populations, its discovery is just as difficult as that of syphilis, and the finding of the infected sex partner of a

gonorrhea patient involves the same painstaking interview and investigation procedures. Gonorrhea control is important. In the military its treatment wastes the attention and time of medical staffs and it still causes considerable loss of man-days to the defense effort. In terms of syphilis case finding, gonorrhea is a helpful indicator to the remaining and developing foci of venereal infection in the civilian population.

Generally speaking, good progress is being made in the entire field of venereal disease control. However, there is no justification for assuming that, when cases become fewer, control activities have to be lessened. Actually, it now is more difficult to find the few remaining cases than it was when there were many. We should not lose sight of the fact that the reason we control typhoid fever, smallpox, and diphtheria is that considerable effort and money continuously is expended in keeping our water pure and our children immunized. In the field of venereal disease, even when we reach a level at which control can be maintained, we will need to continue to supply a network of services for contact interviewing, tracing, and education in order to prevent a resurgence of the disease. Experience has shown that venereal disease has increased in areas where organized control efforts have been relaxed.

I am happy to report that relaxation of effort is not the mood of venereal disease control officials in the States and communities of this country today. They are requesting and getting the complete support of the Public Health Service in their vigorous follow-through of control activities.

Model Sanitation Regulations Protect 82 Million

More than 82 million Americans live in communities in which public eating and drinking establishments operate under sanitation regulations that meet the standards developed by the Public Health Service, according to a recent survey by the Bureau of State Services. Affected by these regulations are the combined populations of 675 municipalities and 346 counties in 42 States, Alaska, and the District of Columbia.

The bureau stated that this protection has more than doubled in the past 5 years. Only 40 million persons, living in 373 municipalities and 176 counties in 37 States and Alaska, were protected by these sanitation ordinances or regulations in November 1946.

National Morbidity Reporting

By C. C. DAUER, M. D.

A revision in the list of reportable diseases and modifications in reporting procedures were formally approved October 31, 1951, by the Association of State and Territorial Health Officers. This represents a major forward step in the improvement of the national scheme of morbidity reporting.

The new system went into effect on January 1, 1952. Its approval by the State health officers is the product of extensive discussions and studies, plus a national conference of epidemiologists, health statisticians, and public health administrators. A manual of instructions covering the approved procedures was distributed to all State and Territorial health officers December 1, 1951, by the Public Health Service.

The main change in the revised system is the addition of eight diseases to the list that States have been reporting each week to the Public Health Service. Two diseases are deleted.

Botulism, brucellosis, dengue, infectious hepatitis, malaria, rabies in man, trichinosis, and typhus fever have been added to the weekly list. Influenza and pneumonia will no longer be reported weekly or annually to the Public Health Service. The consensus is that a better estimate of the prevalence of these diseases can be obtained through reports of respiratory outbreaks and of appropriate laboratory examinations, in combination with mortality records.

Statistics for the 25 diseases now on the weekly list (table 1) will appear in summary form for the United States in the *Communicable Disease Summary* and for each State in the *Morbidity and Mortality Weekly Report*, both

published weekly by the National Office of Vital Statistics.

Monthly summaries of communicable diseases from the States have been discontinued. Instead, States will submit annual summaries, by month and by county of residence, of 39 diseases (table 2). The annual summaries are a return, in part, to reporting practice prior to 1948. Diseases for which acceptable laboratory tests are available to confirm the diagnoses will be tabulated by the final total number reported and the number confirmed by laboratory examination. Annual summaries by months will be published in special reports; the summaries by county of residence will not be published generally but will be made available to persons who request and need such information.

New Emphasis on Epidemic Reporting

A parallel and complementary development in morbidity reporting is the increased emphasis on epidemic reporting. Reports of disease outbreaks are now collected and published on a current basis. The system is working well but full participation by local health officers is sought. All State and Territorial health officers have been requested to report promptly any outbreak or unusual occurrence of diseases of public health interest or importance. Weekly publication of this information will continue.

Responsibility for collecting reports of food- and water-borne outbreaks of disease—previously an activity of the Division of Sanitation—has been assigned to the National Office of Vital Statistics. These reports are made currently rather than at the end of each year, and information from them is included in weekly publications of the Public Health Service's National Office of Vital Statistics. An annual summary of food- and water-borne outbreaks will be continued as heretofore.

Dr. Dauer, formerly chief of the Bureau of Preventable Disease of the District of Columbia Health Department, is medical advisor to the National Office of Vital Statistics, Public Health Service.

Approved by the Association of State and Territorial Health Officers

I. *International Quarantine Agreement*

An international quarantine agreement to which the United States is a signatory requires the immediate notification by telegram of the following diseases to the Surgeon General of the U. S. Public Health Service:

Cholera.
Plague.
Smallpox.
Typhus fever, epidemic (louse-borne).
Yellow fever.

II. *Epidemic Reports*

All outbreaks or unusual occurrences of communicable and other diseases of public health interest should be reported promptly to the U. S. Public Health Service. All such reports should be sent by or through the State health officer.

III. *Weekly Summary of Notifiable Diseases*

The total number of cases not previously reported for a minimum list of diseases (table 1), should be reported weekly to the Public Health Service by each State. Such reports are considered as provisional data, subject to further screening by all interested agencies.

IV. *Annual Summary of Notifiable Diseases*

A. Annual summary by calendar year should be made to the U. S. Public Health Service for an expanded list of diseases (table 2).

B. The annual summary should consist of the following tabulations:

1. State totals of cases not previously reported of the diseases in table 2 by month, with specification of method of allocation to month according to one of the following:

Table 1. Weekly summary of notifiable diseases

Anthrax	Plague
Botulism	Polioomyelitis
Brucellosis	Rabies in man
Cholera	Rabies in animals
Dengue	Rocky Mountain spotted fever
Diphtheria	Smallpox
Infectious encephalitis	Streptococcal sore throat, including scarlet fever
Infectious hepatitis, including serum hepatitis	Trichinosis
Malaria	Tularemia
Measles	Typhoid fever
Meningococcal meningitis and meningococcemia	Typhus fever, endemic
Pertussis (whooping cough)	Typhus fever, epidemic
	Yellow fever

- (a) Date of onset.
- (b) Date of report.
- (c) Date of receipt of report by local health office.
- (d) Date of receipt of report by State health office.
- (e) Other (specify).

2. State totals of laboratory confirmed cases. The States should individually establish standards for acceptable laboratory confirmations for inclusion in these reports to the U. S. Public Health Service, recognizing the desirability of eventually achieving uniformity of these standards among the States. (This is an attempt to secure information on the number of cases of certain diseases, such as diphtheria, typhoid fever, etc., which were confirmed by a laboratory test. The suitability of a test for confirmation of diagnosis is left to the State health officer.)

3. Annual totals of notifiable diseases by county of usual residence for each disease in table 2.

The inclusion of certain notifiable diseases in the weekly summaries and the expanded reporting of disease outbreaks were recommended partly because the data may provide vital information in defense against biological warfare. Many of the diseases listed for weekly reporting are caused by organisms regarded as potential agents that might be employed in subversive activities.

Wide Use for Data

Originally, communicable diseases were reported primarily to determine, as soon as pos-

sible, the prevalence in the community of diseases dangerous to the public health—especially the pestilential diseases. Reporting served as the first step in applying control measures such as quarantine. Later, the collection and assembling of such data provided basic material needed by local and State agencies for planning more effective programs for the prevention or control of some infectious diseases. They have also indicated the futility of severe restrictive measures in attempting to control others.

Health officers of local areas and States, as well as Federal and international agencies, need

Table 2. Annual summary of notifiable diseases¹

Amebiasis	Rabies in animals
Anthrax	Rocky Mountain spotted fever
Botulism	Salmonellosis
Brucellosis	Shigellosis
Cholera	Smallpox
Dengue	Streptococcal sore throat, including scarlet fever
Diphtheria	Tetanus
Glanders	Trachoma
Infectious encephalitis (by etiology if known)	Trichinosis
Infectious hepatitis, including serum hepatitis	Tuberculosis (all forms)
Leprosy	Tularemia
Leptospirosis	Typhoid fever
Malaria	Typhus fever, endemic
Measles	Typhus fever, epidemic
Meningococcal meningitis and meningococcemia	Yellow fever
Pertussis (whooping cough)	Venereal diseases
Plague	Chancroid
Poliomyelitis	Gonorrhea
Paralytic	Granuloma inguinale
Nonparalytic	Lymphogranuloma venereum
Unspecified	Syphilis
Psittacosis	Primary and secondary
Q fever	All other
Rabies in man	

¹All diseases for which laboratory confirmations are available are to be reported by (1) total cases, and (2) total laboratory confirmed cases.

V. Venereal Diseases and Tuberculosis

The annual summary of notifiable diseases should contain tabulations of the number of tuberculosis and venereal disease cases. This does not affect the collection and distribution of certain data by the Divisions of Chronic Disease and Tuberculosis and of Venereal

current information on incidence of disease to study present or new problems, locally, nationally, or internationally. They must also have data to set up appropriate and effective preventive or control measures as the need arises. A communicable disease reporting system that operates smoothly and effectively during a national emergency or catastrophe is a necessity. It would be especially important if the threat of biological warfare or atomic bombing became a reality.

Medical researchers and physicians have urgent need for data on the incidence of infectious diseases. A physician who has a special inter-

Disease of the U. S. Public Health Service from States for purposes of program development or operational activities.

VI. Morbidity Reports From Cities

The subcommittee notes that arrangements exist whereby weekly morbidity reports are furnished to the National Office of Vital Statistics by a selected list of cities throughout the United States. It is the consensus of the committee that this procedure should continue, but it recommends further study of the purposes and procedures for such reports.

VII. National Morbidity Reporting Procedures

The reporting procedures needed to implement the collection of the data described in the recommendations of the committee will be defined in a manual of morbidity reporting procedures prepared by the National Office of Vital Statistics. The draft of this manual has been prepared by the National Office of Vital Statistics with consultation from this subcommittee, Communicable Disease Center, Divisions of Chronic Disease and Tuberculosis and of Venereal Disease of the U. S. Public Health Service, and the Working Group on Morbidity Statistics of the Public Health Conference on Records and Statistics. This manual should be distributed to all States and other appropriate agencies if and when the national morbidity reporting plan is approved by the Association of State and Territorial Health Officers.

VIII. Reporting Animal Diseases

Information as to the occurrence of certain animal diseases which may be transmitted to man is urgently needed for prevention of those diseases in man. Such information should be furnished by veterinarians and others through suitable channels for availability to local, State, and national health agencies. The threat of biological warfare adds to the urgency of developing this program, although the need for it has been apparent for many years.

est in a disease such as tularemia or diphtheria, or the research worker who is studying streptococcal infections, often needs and asks for nation-wide data in order that he may have a sounder basis upon which to develop better methods of treatment or prevention. The need is also apparent in requests for information that may be used in preparing papers to be read at scientific meetings or for publication in journals or books.

Increasing demands for similar data on chronic diseases may lead, in the near future, to more adequate collection methods in this field. Some attempts have already been made to use

hospital statistics as an index of the prevalence of chronic diseases.

Morbidity data are much in demand for general information and health education. Information is needed by persons engaged in health activities in official and nonofficial health agencies. Material supplied to the press, the radio, feature writers of magazines which have a general distribution, and to various publications, such as yearbooks, assist in health education. Private citizens, students, and others request national morbidity data for a variety of uses.

Commercial organizations, such as insurance companies, manufacturers of pharmaceutical and biological products, and other business groups have a legitimate need for morbidity data in planning and developing services and products.

Evolution of Morbidity Reporting

Occasionally, rapidly changing characteristics of a disease have called for relatively rapid changes in reporting, collecting, and disseminating the data. The severe epidemic of poliomyelitis in 1916, the pandemic of influenza in 1918, the explosive emergence of encephalitis in St. Louis in 1933, and the recent increase of malaria among military personnel returning from Korea, all resulted in relatively quick changes in reporting procedures to provide essential data for evaluating new situations.

But most of the changes in the Nation's 74-year-old communicable disease reporting system have evolved slowly. The Public Health Service was first authorized, by an act of Congress in 1878, to collect morbidity data for use in quarantine measures against such pestilential diseases as cholera, smallpox, plague, and yellow fever. One year later, a specific appropriation was made for the collection and publication of reports of notifiable diseases, principally from foreign ports. In 1893, an act provided for collection of information each week from State and municipal authorities throughout the United States. To obtain uniformity in the registration of morbidity statistics, Congress enacted a law in 1902 which directed the Surgeon General of the Public Health Service to provide forms for the collection, compilation, and publication of the weekly data.

Reports on notifiable diseases were received

from a very few States and cities prior to 1900, but gradually more and more States submitted monthly and annual summaries. It was not until after 1925 that all States reported regularly.

In 1913, the State and Territorial health authorities recommended weekly telegraphic reports by States for a few diseases, but several years elapsed before a large number submitted figures in such a manner.

Public Health Service personnel were first assigned in 1914 as collaborating epidemiologists to State health departments to assist in preparing the reports. Later, State health officers were designated as collaborating epidemiologists, and local officials were appointed as assistant collaborating epidemiologists. Beginning in 1915, the collaborating epidemiologists in a few States used report cards with penalty privileges. In 1919, the policy of supplying cards to all States was established by request of the State and Territorial health authorities. However, not all States have used morbidity report cards which carry the penalty privilege.

Reciprocal notification of diseases in persons presumably infected outside the State was practiced by Minnesota as early as 1914. However, other States did not participate until after 1917, when the State and Territorial health authorities recommended the adoption of this practice.

Until 1942, the collection, compilation, and publication of morbidity statistics was under the direction of the Division of Sanitary Reports and Statistics of the Public Health Service. These functions were transferred to the Division of Public Health Methods in 1942, and to the National Office of Vital Statistics in 1949.

Product of Many Groups

The current plan is the product of much discussion and weighing of needs.

In 1948, a limited revision of morbidity reporting procedures was instituted following a study by a group in the Public Health Service. Soon after the transfer of morbidity reporting activities to the National Office of Vital Statistics, another committee in the Public Health Service was appointed to review the procedures then in operation and to present a revised plan which would more nearly meet the needs of

both State and Federal health agencies and aid in providing essential information for civil defense. The threat of biological warfare has been an added incentive to the development of a revised program of morbidity reporting.

A plan was submitted to the Association of State and Territorial Health Officers at their meeting in Washington, October 23-27, 1950. The action taken was in the form of a recommendation that all States cooperate with the Public Health Service in a 1-year trial of the "Plan for Revising Morbidity Reporting by States," effective January 1, 1951. Because certain technical problems arose regarding operation of the plan, the effective date was postponed.

On January 13, 1951, the Association of State and Territorial Health Officers authorized a conference of State epidemiologists to determine what diseases should be reported by States to the Public Health Service and procedures to be followed in submitting weekly and annual summaries. A conference was held in Atlanta, Ga., April 18-20, 1951,¹ and subsequently an interim group, the subcommittee of the Committee of Infectious Diseases of the Association,² drew up the final report on the recommendations of the conference. The statement was also reported to the Committee on Administra-

¹For program see the CDC Bulletin, 10: 18-22 May 1951.

tive Practice of the American Public Health Association at its meeting in San Francisco on October 29. The State and Territorial Health Officers, meeting in the same city, unanimously approved the report October 31, 1951.

First Step in Larger Plan

The new morbidity reporting procedures are the first step in an over-all program for improvement of morbidity reporting. Some means of improving the completeness and promptness of reporting by physicians, methods for checking the completeness of reporting, development of acceptable standards for laboratory confirmation of certain diseases, greater uniformity in items of information reported for individual cases of notifiable diseases, and uniform methods for allocation of cases by residence and by months, are a few of the problems that need study and resolution. Some of these are already being considered by the Working Group on Morbidity Statistics of the Public Health Conference on Records and Statistics. Other studies bearing on these problems are being contemplated in cooperation with representatives of State health departments and of branches of the Public Health Service. Eventually, the studies should result in more accurate and dependable morbidity data.

A discussion of morbidity reporting as the basis of communicable disease control, presented by Dr. Wilson G. Smillie at the Conference of State Epidemiologists on National Morbidity Reporting, will be published in an early issue of PUBLIC HEALTH REPORTS.

Salaries of State Health Department Personnel

By SAM A. KIMBLE, A. B.

Median salaries of selected groups of State health department personnel have increased on an average of one-third during the 5-year period since 1947. The percentage increases ranged from a low of 20 percent for sanitary engineers to a high of 56 percent for sanitarians.

The real significance of these salary increases can only be discerned in the broader perspective of a decade or more of steadily rising living costs. Although knowledge of the salaries of public health workers was so fragmentary prior to 1947 that a sound evaluation of salary trends on a national scale was impossible, the information available indicated that during the early 1940's public health workers, as well as other public servants, were experiencing a persistent decline in real wages because of static salary levels.

To develop reliable and comprehensive salary data, the American Public Health Association and the Association of State and Territorial Health Officers in 1947 joined in asking the Public Health Service to participate in a 5-year series of nation-wide studies of salaries received by State and local public health workers. Results of these studies have been published each year (1, 2). This report summarizes the trends which have taken place in the salaries of State public health personnel during the 5-year period. Five-year trend data for salaries of local public health personnel will not be available until the next local salary study has been completed in the spring of 1952.

Data for the studies of the salaries of State public health workers were obtained directly

from State health department payrolls. Two types of groupings were made in tabulating the salary data. One group includes salaries of personnel at the executive or director level. These are the State health officers and directors of dental public health, sanitary engineering, laboratory services, public health nursing, and vital statistics. Original plans to include directors of certain medical programs in this group were abandoned in 1950 because the increasing number of organizational combinations in State health departments was seriously affecting the comparability of positions from year to year and among the States. The other group includes personnel in the following professional categories (exclusive of the program directors included in the first group): medical, nursing, sanitary engineering, sanitation, nutrition, health education (added in 1948), statistical (added in 1949), laboratory, and business management (added in 1950). In all of the studies, data on all medical directors (other than those directing laboratory and vital statistics programs) have been included in the general group of medical personnel.

Salaries of part-time and seasonal employees, of trainees, of State health workers assigned to institutions, and of personnel assigned to activities performed normally by local health units were excluded from the study. When identifiable, salaries of all personnel assigned to local health units or State districts offering direct local health services were also excluded. Although organizational patterns, responsibilities of individual positions, and position nomenclature vary considerably from State to State, sufficient comparability exists to justify broad comparisons among States and to study national trends. The median salary—that salary below and above which half of all the

individual salaries fall—has been used to measure trends in these studies.

Salaries of all groups included in the study increased during the 5-year period. Percentage increases in the median salaries of selected groups in State health departments between 1947 and 1951 are shown below:

	Percentage increase
State health officers.....	33
Directors of dental health services.....	50
Directors of sanitary engineering.....	29
Directors of laboratory services.....	25
Directors of public health nursing.....	29
Directors of vital statistics.....	21
Medical personnel.....	43
Sanitary engineers.....	20
Sanitation personnel.....	56
Professional laboratory personnel.....	21
Supervisory and consultant nurses.....	35

The table shows the distribution of salaries which were being paid in August 1951, the most recent period studied. Median salaries

in 1951 for the types of personnel which are not represented in the 5-year trend study are: nutrition, \$3,900; health education, \$4,300; statistical, \$3,900; and business management, \$5,700.

State Health Officers

The most strategic position in the salary structure is held by the State health officer. Difficulties in keeping public health salaries from lagging behind costs of living and the competitive market for professional personnel often center around the reluctance of State legislatures to modify specific statutory salary rates applicable to the State health officer's position. The most significant changes in these salaries have occurred during the past 3 years (fig. 1).

The trend can also be illustrated by other facts. In 1947, the annual salaries of State health officers ranged from \$5,000 to \$15,000. The median salary for health officers that year was \$7,500. Seven of these officials were then receiving \$10,000 per year or more, and 15 were

Selected State health department personnel by specified salary intervals, August 1951

Salary intervals	State health officers	Medical personnel	Directors dental public health services	Environmental sanitation			Laboratory		Public health nurses		Directors vital statistics
				Directors sanitary engineering	Sanitary engineers	Sanitation personnel	Directors	Professional personnel	Directors nursing	Supervisory and consultant

\$6,000-\$6,999	1	45	6	10	66	15	10	40	8	7	9
\$5,000-\$5,999	0	10	0	4	122	50	7	122	21	54	12
\$4,000-\$4,999	0	1	0	0	155	210	1	256	11	157	9
\$3,000-\$3,999	0	0	0	0	120	274	1	559	0	137	3
\$2,000-\$2,999	0	0	0	0	3	54	0	315	0	2	0
Under \$2,000	0	0	0	0	0	0	0	0	0	0	0
Median salary	\$10,000	\$8,500	\$8,100	\$7,740	\$4,800	\$3,900	\$7,500	\$3,500	\$5,400	\$4,250	\$5,460

receiving less than \$6,600 per year. In 1951 State health officers' salaries ranged from \$6,500 to \$17,500 and the median salary had risen to \$10,000, or one-third higher than the 1947 median. Only one State health officer was receiving less than \$7,200 per year in 1951, while 14 were receiving \$12,000 or more, including 4 with salaries of at least \$15,000.

Medical Personnel

As might be expected, the median salaries of medical personnel (exclusive of State health officers and the directors of the selected health services which were tabulated separately) increased in somewhat the same pattern as the median salaries for State health officers (fig. 2). The increase in median salaries of the medical group was 43 percent during the 5-year period. Although 54 percent of the group were receiving salaries of less than \$6,000 per year in 1947, only 3 percent were below the \$6,000 level in 1951. The proportion of medical personnel receiving salaries of \$9,000 or more increased from 1 percent in 1947 to 38 percent in 1951. Approximately 15 percent of the public health physicians in State health departments were receiving salaries of \$10,000 or more in 1951, and 10 were being paid at the rate of \$12,000 per year.

Dental Directors

As a group, the dental directors rank next to physicians in the State health department salary structure. The median salary among the directors of State dental public health services increased from \$5,400 in 1947 to \$8,100 in 1951, an increase of 50 percent in 5 years. The 1951 median salary was \$1,000 above the highest 1947 salary. Only 6 of the dental directors were receiving less than \$7,000 in 1951, and 2 were receiving more than \$10,000. In 1947 the highest salary among dental directors was \$7,100, and 14 were receiving less than \$5,000.

Environmental Sanitation Personnel

The percentage increase in the median salaries for the directors of sanitary engineering during the period of study was 29 percent; for other sanitary engineers, 20 percent; and for sanitation personnel other than engineers, 56 percent. The lower and upper limits of salaries for the directors moved upward with the general increase in salaries:

	1947		1951
Low	\$4,250	Low	\$5,178
High	11,000	High	12,372

The distribution of their salaries is approxi-

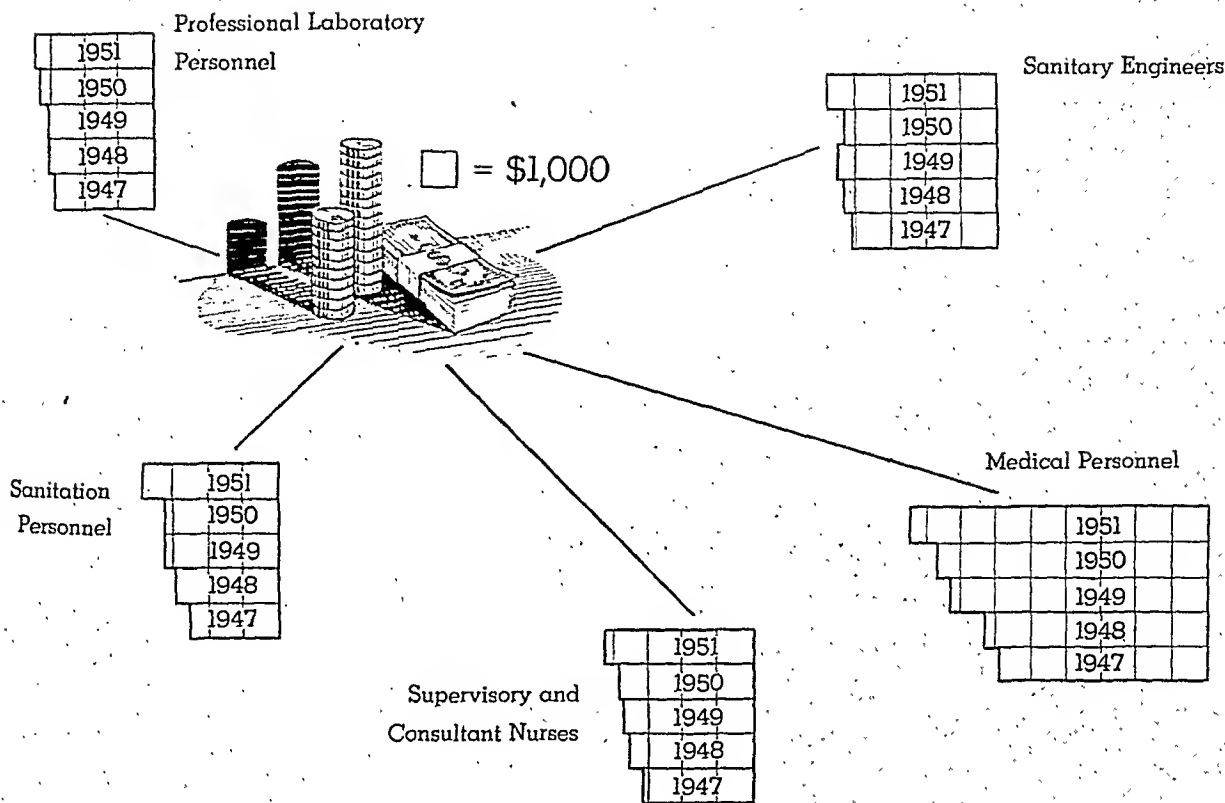

Figure 2. Median salaries of selected groups of State health department personnel, 1947-51.

mately the same as that for dental directors. Another index of the general improvement in salary status of these directors is the shift in the numbers receiving salaries of less than \$6,000. The 22 who were in this group in 1947 had been reduced to 4 in 1951. The change at the upper salary limit was less dramatic. At the end of the 5-year period there had been an increase of from only 2 to 5 receiving salaries of \$10,000 or more.

A somewhat different salary trend was found among the other sanitary engineers as compared with directors of sanitary engineering. They received the smallest percentage increase of all the groups studied. This was not particularly surprising since the group experienced a considerable numerical increase over the 5-year period. This would tend to depress the median salary because when large numbers of new employees are added to the staff they are generally employed in the lower salary brackets. Even

so, the changes in the salary distribution for this group were marked. In 1947 only 15 percent received \$5,000 or more per annum, while in 1951, 45 percent were in this category. The change at the \$7,400 level is more striking. Only 2 sanitary engineers were above this salary in 1947, but 38 were in this group in 1951. At the other extreme the number receiving less than \$3,200 was reduced from 41 in 1947 to 7 in 1951. The medians for sanitary engineers and sanitation personnel were:

	1947	1951	Percent increase
Sanitary engineers.....	\$4,100	\$4,900	20
Sanitation personnel.....	2,500	3,900	56

The large percentage increase in median salary for sanitation personnel still left the median for this group, dollar-wise, only one step removed from the lowest median rate in 1951. One explanation of the continuing low median rate in the sanitation group is the heterogeneous

yearly intervals instead of each 3 months for 2 years. At present, a staff committee is developing policies and procedures for our total tuberculosis control program. As soon as time and staff are available, we will probably lengthen the period of observation of suspected cases and increase slightly the number of visits to the clinic for rechecks so that we may eliminate the possibility of overlooking a few active, progressive cases among the suspects.

Laboratory studies on first examinations have been intensified. This was done by adding one more technician to the laboratory staff and by clinic physicians requesting more complete laboratory work on initial visits. This change in laboratory procedures requested on first visits has resulted in more frequent discharge of patients on the basis of negative laboratory findings and, therefore, in a diminished burden upon X-ray facilities. We hope that the more complete laboratory work at the time of the initial visit will mean active cases can be found earlier and more of the inactive cases dismissed.

Impact on Clinic Services

Medical services were improved in two important ways by the mass survey. First, additional clerical staff was assigned and maintained at the clinic throughout the year, making it possible for the professional staff to handle a greater volume of work.

The second important aid to clinic services made possible by the survey was the classification and filing of all X-ray films taken by survey teams. Funds to do this filing job were provided by the California State Department of Public Health. Specific films are now available to physicians on request and are proving a valuable asset to the clinician. For example, 26 cases of tuberculosis have developed in persons who had negative films at the time of the survey. Having the survey film available for study is of obvious value to the physician in estimating the time and stage of infections discovered following the survey. At the same time, this has emphasized to physicians in the community what they already knew, namely, that a single negative chest X-ray does not guarantee that future films will not show active tuberculosis or other significant pathology.

Case Register and Reporting

A central tuberculosis case register has been operated by the department since 1948. However, it had not been developed to its optimum effectiveness before the mass survey. To assist with the registry for the mass survey, the United States Public Health Service assigned to the department a special case registry consultant. This consultant was, during her assignment to San Diego, not only able to improve and maintain the register but also to train a case registry clerk to take over when she left. Thus, because of the survey, this department has been able to have the continued use of an active case register.

Contact investigation was another activity in which improved services could be traced to the survey. In this instance, it was a matter of the increased case load justifying the assignment of clerical help to improve an existing contact registry. This meant better follow-up service given to known contacts as well as to the large additional number of contacts discovered by the mass X-ray survey.

Private physicians diagnosed and reported as active tuberculosis cases 73 of the survey suspects referred to them—approximately one-third of all the active tuberculosis cases found by the survey. In addition, in 1950, private physicians reported 52 active tuberculosis cases found in the course of their normal practice, or approximately as many as they had reported in the preceding year.

As a result, there were, in 1950, 640 active tuberculosis cases new to the health department, or approximately 7 cases per annual death. This high ratio was not due to the inclusion of any appreciable number of inactive and activity-undetermined cases. In fact, 68 percent of the new pulmonary cases had activity demonstrated by the presence of tubercle bacilli.

Tuberculosis case finding was successful in the older age groups, ages 40 and over, as measured by the ratio of newly reported active cases to deaths. In this group there were 5.5 new cases per death. Usually the ratio of new cases per death is very low among the older adults.

In 1950, 88 tuberculosis deaths were reported. Of these, 31 percent had not been known to the health department as active cases before the death certificate was filed. Although this per-

centage was only slightly lower than in 1949, it was substantially lower than in the years preceding 1949.

Nursing Program

The impact of the survey on the nursing program was great. Several months before the survey, staff nurses were offered an intensive in-service education program in which all phases of tuberculosis control were reviewed. At the same time, plans were made to allot as much nursing time as possible to the survey effort. This meant that some nursing services had to be eliminated and others reduced. Among the changes made were:

Routine home calls to all patients with minor communicable diseases have been eliminated. Instead, instructions for the care of patients are sent to the home. At the time that a minor communicable disease is reported by a parent, the clerk inquires if the patient is under the care of a private physician. If a private physician is in attendance, instructions are mailed, but no home call is made. If the patient is not under the care of a private physician and there are siblings under 2 years of age in the family, or there is any other known health problem, a home visit is made.

Changes were made in the city-wide school smallpox vaccination program. Instead of allowing the usual full school term in which to perform this service, the work was condensed into 12 weeks previous to and at the conclusion of the survey.

Districts of all nurses on duty at the mass survey retake center were covered by other members of the nursing staff.

The number of nurses used in prenatal and well-child conferences was reduced.

An expected result of the survey was the involvement of more staff nurses and their time in tuberculosis follow-up activities throughout 1950. From this increased interest in, and knowledge of, the problem of tuberculosis has developed the appointment of a staff committee which is now reviewing all department tuberculosis policies and procedures.

Medical Social Work

The mass X-ray survey provided an opportunity to add the services of a medical social worker to the established medical and nursing program. The medical social worker was assigned by the United States Public Health Service. Public health medical and nursing staffs have recognized for many years that emotional and socioeconomic factors have been paramount causes in developing "uncooperative patients," that is, patients who fail to place themselves under medical care or who fail to complete a treatment plan. No person with specialized training in managing the emotional impact of illness and in the use of social agencies was available before the survey to assist the local staff in meeting these problems. A staff, untrained in these functions and occupied with other professional responsibilities, met the needs as best it could.

The medical social work demonstration has now been in operation more than a year. Medical social services have been offered to all newly diagnosed patients as well as to regular clinic patients referred for special handling of personal problems.

The demonstration has given convincing evidence of the need for qualified case-work service to handle patient problems at the point of clinic contact so that the patient may obtain maximum benefit from medical services. Since the addition of this service the relationship of patients to the clinic and of the clinic to community agencies has improved. With few exceptions, the survey patients newly diagnosed in the clinic have worked out satisfactory plans of medical care. In this same group hospital discharges against medical advice have been reduced to approximately 15 percent, or one-half of the rate in groups whose initial diagnosis was not handled with case-work help. Tuberculosis control is best served by meeting the patient's problems at the time of diagnosis so that he may begin, and continue, a plan of treatment with the assurance that his family's welfare will not be jeopardized.

Although the survey clinic load per month dropped gradually during 1950, the number of cases referred for case-work service remained constant at between 30 to 35 a month. In-

creasingly, referrals are received for services other than medical care, for help in such areas as marital problems affecting the course of illness, planning for children, emotional reactions to illness which have interfered with treatment, and planning for vocational guidance and training.

The evidence accumulated from the medical social work demonstration has indicated a need for additional consideration of the social resources available in the community. Serious gaps in service still exist which deter patients from obtaining needed medical care. The survey has shown a need for research into patients' needs and for the development of community resources so that patients may procure medical care.

Relations With Other Agencies

One of the major after effects of the San Diego mass survey has been the strengthening of the health department's relationships with the city's official and voluntary agencies concerned with the community's health. From the beginning, the survey was a cooperative project of many groups and involved joint planning and joint responsibility for its success or failure. This very fact—that many health agencies worked together on a common problem—increased the understanding of each for the other as nothing else could have. Especially significant were the effects on the health department of relations with medical, nursing, and community citizen groups.

Additional Gains

It was the opinion of the health department staff participating in the survey that private physicians who took part gained an increased understanding of the over-all functions of the department. Physicians recognized that tuberculosis control and follow-up is a job for the department of public health, and the health department staff realized more clearly than ever the role of the private physician in disease control activities. The local medical profession gave its wholehearted support to every phase of the project. Many physicians spent long

hours at the conclusion of their own working days serving on medical policy planning committees and X-ray review boards.

The increased case load brought about close cooperation among all nursing services in the community—public health nurses, school nurses, visiting nurses, and private duty nurses. Many nursing groups, not specifically connected with public health activities, assigned members of their own staffs to duty at the X-ray retake center.

The experience of one community group which helped with survey organization was typical of many. In this community, so pleased were the citizens with the survey effort that shortly afterward they asked the department for further assistance in developing other community health programs. It now has an active health committee which has undertaken many activities in the past year and is a staunch friend of the health department. Throughout the entire San Diego area citizens have become more aware of the many ways in which they can participate in programs to improve the health of their communities.

Cancer and Cardiac Follow-up

One of the unique contributions of San Diego to the mass survey concept was the incorporation of provisions for the follow-up of suspect neoplasm and cardiac cases found on the X-ray. Funds for the follow-up program were provided by a special grant from the California State Department of Public Health.

The San Diego tuberculosis control service had always maintained a high index of suspicion regarding neoplasm and was aware of the opportunity presented for early neoplasm case finding through the photofluorogram. But with clerical and nursing staffs already overtaxed by the tuberculosis load, it had never been possible to trace each suspected neoplasm to a definitive diagnosis. The public health nurses working on the newly inaugurated follow-up were available to take rather detailed histories on suspected neoplasm and cardiac cases, and then, with medical supervision, were available to guide the patient to a private physician or other facility for further diagnostic study.

Four hundred and forty-seven suspected neoplasm patients were followed, and 29 have undergone major surgical procedures as a direct result of the survey. These were:

Pneumonectomy-----	7	Pneumonotomy -----	1
Lobectomy-----	11	Thoracotomy for re-	
Thoracotomy for re-		moval of media-	
moval of pericar-		stinal tumors-----	3
dial cyst-----	1	Mastectomy -----	1
Thyroidectomy-----	5		

Because of the focus of attention upon neoplasm case finding and the experience gained by health department personnel in the survey, a file of all pulmonary neoplasm deaths was set up for 1950, and has continued. It is now possible to check these deaths among those who had survey films. Interesting observations will be possible in the next 12 to 18 months.

Summary and Conclusion

An attempt has been made to review briefly some of the major effects of the community-wide chest X-ray survey in the months following the conclusion of actual X-raying:

1. The health department was able to serve the entire community rather than just specified groups of "indigents" or "contacts." The health department in this new role gained stature, we believe, and began to mean more to everybody in and around San Diego.
2. The health department and cooperating agencies worked out techniques for concentrating their time and energies on tuberculosis for a short period. This kind of increased attention to a specific health problem seems to be extremely productive.
3. Tuberculosis clinic services available to the public were increased and improved.
4. The usefulness of both the tuberculosis

case register and the contact register was greatly enhanced.

5. The impact of the survey on the public health nursing staff brought many temporary, and some permanent, changes in nursing procedures.

6. Health department relations with medical, nursing, and community groups were strengthened.

7. Medical social work had an opportunity to prove its place in the health department program.

8. Gains in chronic disease control—cancer, heart disease—were made.

A portion of the health officer's statement which appeared as the final page of the survey report (2) may perhaps serve as the conclusion of this article:

"The story of metropolitan San Diego's mass chest X-ray survey which has unfolded on these pages is the story of the greatest concerted attack against disease ever undertaken by our community

"Just as the X-ray allows us to look inside an individual, the mass survey gave San Diego an opportunity to get a good look at itself attacking a public health problem. It has brought to many homes and to many individuals the realization that the public health is *everybody's* business. Through participation in the tuberculosis program, San Diegans are already beginning to think of other ways in which they can work together."

A Symposium

On June 22, 1892, Sir James Crichton-Browne, M. D., presided over the eastern counties branch of the British Dental Association in Cambridge. In the course of his remarks¹ he said:

"The late Dr. George Wilson showed that fluorine is more widely distributed in nature than was before his time supposed, but still, as he pointed out, it is but sparingly present where it does occur and the only channels by

which it can apparently find its way into the animal economy are through the siliceous stems of grasses and the outer husks of grain, in which it exists in comparative abundance. Analysis has proved that the enamel of the teeth contains more fluorine, in the form of fluoride of calcium, than any other part of the body and fluorine might, indeed, be regarded as the characteristic chemical constituent of this structure, the hardest of all animal tissue and containing 95.5 percent of salts, against 72 percent in the dentine. As this is so it is clear that a supply

Fluoridation of Municipal Waters

The Study of Mottled Enamel

By Frederick S. McKay, D. D. S.
Colorado Springs, Colorado

At the turn of the century dental pathologists recognized two principal developmental lesions of the enamel. Of the one most frequently occurring—then termed "atrophy"—the etiology was fairly well understood. For the second, white spots in the enamel, there was no known explanation. In 1906-1907, the occurrence of an identical developmental lesion in practically the entire native population of Colorado Springs was brought to the attention of Dr. G. V. Black. Following a personal examination in 1910, he declared it to be a new lesion in dental pathology and gave it the name of "mottled enamel."

Widespread examinations of similarly afflicted populations showed that the one common factor apparently was the continuous use of the domestic water supply during the years of enamel formation. The waters associated with mottled enamel were derived from almost every conceivable source. However, it was found that

A Chemist's Evaluation

By A. P. Black, Ph. D.
*Head, Department of Chemistry
University of Florida*

Fluorine, lightest and most active of a family of elements known as the halogens, was first isolated by the French chemist, Moisson, in 1886. It is not only the most active of its family, but is the most active element known, combining directly with all other elements except oxygen and the rare gases. Fluorine is present in most soils and in the bones and teeth of animals. Sea water contains approximately one part per million of the element, and it is present in amounts varying from mere traces to significant concentration in a high percentage of the public water supplies of this country. Fluorine is present in a great many of our human foods, although the average daily intake from food is quite small.

A chemist, H. V. Churchill, in 1931 first called attention to the fact that the water supplies of Bauxite, Ark., Colorado Springs, Colo., Kidder, S. Dak., Lidgerwood, N. Dak., and Oakley, Idaho, all known to produce mottling of teeth,
(See page 39)

of fluorine, while the development of the teeth is proceeding, is essential to the proper formation of the enamel and that any deficiency in this respect must result in thin and inferior enamel.

"If, in our dislike to grittiness, which has run parallel to our addiction to soft and succulent food and in our preference for white and fine flour, we have cut off the main source of supply of fluorine to our systems, it is not difficult to understand how we may have thereby incurred comparatively feeble and unprotected

teeth, with a diminished power of resistance to adverse influences and peculiarly liable to decay. For the dense close-fitting prisms of the enamel are to the tooth what its armour plates are to a modern ship of war; and if they are easily penetrated, corroded, or worn away, then the fate of the dentine within is sealed. I think it well worthy of consideration whether the re-introduction into our diet, and especially into the diet of child-bearing women and of children, of a supply of fluorine in some suitable

The American Dental Association

The Practicing Dentist's Viewpoint

By Milton E. Nicholson, D. D. S.

*Associate Professor of Public Health Dentistry
University of Pittsburgh*

Fluoridation of municipal waters is now generally accepted as being one of the cheapest and most effective methods available for reducing the incidence of dental caries. Researchers, working

independently of each other, have supplied us with so many findings in support of fluoridation that it seems almost basic for all communities to fluoridate their water supplies.

The practitioner can help further programs aimed at prevention and control of dental disease. He frequently does not realize just how important he is in helping to create public opinion. His close relationship with patients and his unique position as an accepted leader in dental health matters in the community enable him to guide dental health thinking of those with whom he comes in contact.

A number of far-sighted dentists and researchers have realized for years that the dental caries problem will never be solved by repair service alone. As a result, many preventive

A Public Health Dentist's Viewpoint

By F. A. Bull, D. D. S., M. S. P. H.

*Director of Dental Health
Wisconsin State Board of Health*

To most of us in the dental profession the public health approach to the dental health problem is something new. The fluoridation program has given us the first opportunity to offer a preventative

for dental caries which lends itself to mass control in 60 percent of the population.

No other public health program has had, at the time of its introduction, as much scientific data based on human experience. No valid disadvantage or objection to the program has been proved. Successful 5- and 6-year demonstrations in Michigan, New York, Wisconsin, Texas, and Canada were instrumental in bringing about national level approval of the fluoridation program.

But even when there is no real opposition to a public health program the "status quo" is a factor to be reckoned with. Hence, it is important that everyone concerned be given factual information about fluoridation and what it means in terms of improved dental and general

(See page 40)

Symposium

(from page 37)

natural form—and what form can be more suitable than that in which it exists in the pellicles of our grain stuffs?—might not do something to fortify the teeth of the next generation.”

Today—nearly 60 years later—the vital role of fluorine is well established. First through topical applications and more recently by addition to public water supplies, the dentist, the public health worker, and the public now have at hand practical and effective measures for the large-scale prevention of dental caries in children.

Fluoridation of drinking water is emerging as one of the outstanding public health developments of recent years. Historians may well rank it with the control of typhoid fever, milk-borne diseases, smallpox, and goiter. It represents both a remarkable research accomplishment and a major application of community health principles.

The first mass preventive measure in the field of dental public health, fluoridation requires not only the teamwork of dentists, chemists, engineers, and other public health people, but the active understanding and support of the public as a whole, their elected officials, and their community leaders. The growing number of communities—now more than 120, ranging from towns of 500 to metropolitan areas—which are bringing the benefits of fluoridated water to their children underscores the significance of this community health development.

The importance of fluoridation prompted the American Dental Association to include a symposium on “The Dentist’s Responsibility in the Fluoridation of Municipal Waters” in the program for the 92d annual session, held in Washington, D. C., October 15–18, 1951. The four speakers were Dr. Frederick S. McKay, Colorado Springs, Colo., who was honored this year for his pioneering work in the field; Dr. A. P. Black, head of the Department of Chemistry of the University of Florida in Gainesville; Dr. Milton E. Nicholson, practicing dentist and associate professor of public health dentistry,

University of Pittsburgh, Pittsburgh, Pa.; and Dr. Frank Bull, director of dental health, State Board of Health, Madison, Wis. The summary was given by Dr. Allen O. Gruebbel, secretary of the Council on Dental Health of the ADA.

By arrangement with the American Dental Association, the four major papers of the symposium are presented here in summary.

Dr. McKay

(from page 36)

very frequently the water in endemic districts came from drilled wells of varying depth.

Three strikingly similar experiences in towns in different parts of this country strengthened the water hypothesis and led directly to the discovery of the presence of fluoride. In two of these towns the domestic water supply had been changed from shallow wells to deep drilled wells; in the third town the change had been from shallow wells to water from a warm spring. In each instance mottled enamel became endemic in children born subsequently, whereas prior to the change the condition was unknown. H. V. Churchill, chief chemist of the Aluminum Company of America, found in 1931 that the fluoride content of the deep-well water at Bauxite, Ark., was 14 parts per million, an extremely high content which was reflected in the general severity of the mottled enamel in the population. Examination of water from other communities in which mottled enamel was endemic revealed fluorides. Similarly, water from communities in which there was no mottled enamel were found to be free of fluoride, or practically so.

It soon became apparent that invariably the caries experience rate among the natives of fluoride districts was remarkably low, even when the degree of dental fluorosis was pronounced or even extreme. The first examinations to determine this relationship were made in Wisconsin and other parts of the midwest by Bull, Dean, Arnold, and others.

The exhaustive and brilliant research conducted by Dean and co-workers over a wide territory not only confirmed beyond question the fluoride-low caries hypothesis, but also established that the safe and effective fluoride content is around 1 part fluoride in a million parts of water. As the fluoride content passes 1.5 parts

¹ Crichton-Browne, Sir James: An address on tooth culture. *The Lancet*, vol. 2, 1892, p. 6. Quoted by A. P. Black before the American Dental Association, October 17, 1951. Washington, D. C.

per million or approaches 2.0, the probability of producing a disfiguring fluorosis increases.

Studies in recent years indicate that the caries inhibitory action of fluoride extends well into middle life and that it is not necessary to continue the use of fluoridized water after the enamel has been calcified.

The average number of decayed, filled, and extracted teeth among the natives of fluoride communities is about three, at an average age of 25 years. And one third or more of the native persons are caries free.

During the decades of study by dentists and research workers to find a means of preventing the initial lesion of caries, the effort seemed to have concentrated on altering the environment of the teeth. On the contrary, the action of fluoride affects the structure or character of the teeth themselves. When caries occurs in fluorosed teeth it is virtually limited to the fissures and pits. Caries of the proximal surfaces of the anterior teeth is almost negligible.

In summing up, it can be emphasized that the integrity of the structure of the enamel is determined only during the period of calcification and not thereafter; fluoride is the only known agent ordinarily included in the diet that is capable of exercising a mass control of dental caries.

The practical application of the findings in this study has led us into the fluoridation of public water supplies, and the impact on public health and the future practice of dentistry cannot at present be completely evaluated.

Dr. Black

(from page 36)

contained fluoride. Though Churchill carefully stated that, because of the few samples examined, his work could not establish a definite correlation between the presence of fluorides and the production of mottled enamel, his report immediately focused attention on fluorides in water, and the connection quickly became apparent. Churchill asked what physiological effects may be produced by fluorides in water. The answer—the reduction of the incidence of dental caries—promises to be one of the landmarks in the history of public health, not only in this generation but in this century.

The first and still the most widely used ma-

terial for fluoridation is sodium fluoride, which in its pure form is a white crystalline salt with a relatively high solubility constant over a wide temperature range. Because of its suitability for feeding in solution in small volumetric feeders, it is used in the majority of smaller installations throughout the country. A somewhat less expensive agent, used in larger installations, is sodium silicofluoride.

Dean reported in 1933 that fluoride concentrations of not more than 1.0 to 1.5 parts per million were not significant in the production of endemic dental fluorosis. Thus when the preventive effect of sodium fluoride became apparent, it was suggested that this dosage be used. A special committee of the American Water Works Association pointed out in 1949 that climatologic conditions might prove to be important since they govern to some extent the water intake of the individual. Evidence continues to accumulate, and it is now believed that a dosage of 0.7 part per million is sufficient to provide the necessary protection in regions where the mean annual temperature is above 70° F.

The mechanism of caries prevention is particularly difficult to determine, since the difference, if any, between the fluorine content of sound and carious teeth is very small. Armstrong and Brekhus have stated that the enamel of carious teeth contains less fluorine than the enamel of sound teeth. However, McClure has recently reported that the dentine and enamel of several hundred sound and carious teeth with no evidence of fluorosis, which were obtained from nearly 100 individuals, did not differ in fluorine content with any regard to their carious or noncarious history. Many workers have shown that the fluorine content of teeth exhibiting mottled enamel is higher than that of normal sound teeth.

Dr. Krasnow of the Guggenheim Dental Clinic observed that the protein concentration in the saliva from patients with dental caries was definitely higher than in saliva from caries-free patients. Investigators in the Zeller Memorial Dental Clinic at the University of Chicago, employing the germ-free technique, found that a group of 13 white rats living on a normally carious-producing diet for 137 to 150 days experienced no caries in the absence of

microbic life. The control group, fed the same sterilized rations but reared under normal laboratory conditions, had a caries experience of approximately 97 percent. These results appear to support those who maintain that dental caries is associated in some manner with the bacterial flora of the mouth. If that is true, the now demonstrated preventive effect of minimal concentrations of the fluoride ion in drinking water becomes all the more impressive.

Dr. Nicholson

(from page 37)

methods have been subjected to experimentation and some have proved of some worth. Dietary and nutritional habits, proper use of the toothbrush, reduction in intake of refined starches and sugars, good operative procedures, and topical applications of fluorides have all been demonstrated to be good preventive methods. These are in the same category as fluoridation of municipal waters, the only difference being that never before has there been a method devised as cheap, as simple to administer, as effective, and as far reaching as fluoridation.

The practicing dentist can be very proud of his contributions to society in alleviating and eliminating pain, in repairing and restoring impaired or lost dental function, and in helping to develop the operative techniques and procedures associated with an improved treatment service. In the modern conception of health service, however, these contributions are not enough. Each practicing dentist, in addition to being a good operative dentist, must thoroughly ground himself in preventive and control service as well. As a highly specialized individual he must exert all his efforts toward solving the dental health problem.

All practicing dentists must realize the seriousness of the dental health problem facing the public and the profession. Preventive and control methods are the only logical approach to the problem, since we will never be able to keep pace with the present rate of dental caries. The incidence must be reduced appreciably. All proved methods of reducing the incidence of dental caries, especially the fluoridation of municipal waters, must be given serious and continuous consideration.

Even though he may not realize it, the prac-

itioner has a large stake in dental public health. Raising the standards of dental health in his community is certainly one of the obligations of a dentist. When a patient wishes to discuss the fluoridation process, the dentist should use the facts readily available to him rather than evade the issue with faint praise. By so doing he will take the lead in preventing misunderstanding and confusion. He will also be instrumental in bringing to his community one of the best procedures yet discovered for the control of dental caries.

Dr. Bull

(from page 37)

health by reducing caries attack rates 60 percent in children. Most communities have an earnest desire to improve the health of the public, but they are fearful of adopting some program which might eventually prove to be a boomerang.

There has been some complaint that the dental profession has done little to prevent dental caries on a public health basis.

The local dental society is the dental authority in any community, and the local dentists, with assistance from the State dental society and State department of health, must take the initiative in following through on a fluoridation program. They must assume the same leadership, courage, and persistence that was shown when earlier public health measures were inaugurated.

From a public health viewpoint fluoridation has many local features which are necessary for a successful community health program.

1. It can be carried out in its entirety through existing facilities.

2. It requires no special effort or participation on the part of the individuals of a community.

3. The reduction in dental caries (65 percent) is great enough to warrant its adoption by the community.

4. The cost of the program is so small that it can easily be justified in any community.

5. There are no known objectionable features to a program of water fluoridation.

6. It is a program which can be readily understood by the community.

7. Fluoridation has been in actual operation

long enough (6 years) to prove that the mechanics and controls are accurate and simple and that the dental health benefits obtained with controlled fluoridation equal natural fluoridation.

One thing must be guarded against in the fluoridation program. That is the belief that once the communal water supply has been fluoridated the whole dental health problem has been solved. Nothing could be further from the truth. It will take about 14 years after a community starts fluoridating before a two-thirds reduction can be made in the caries attack rate

of all children. And even after fluoridation has been carried on for a long period of time, one-third of our present dental decay rate will still be with us.

It is our obligation to see to it that all communities fluoridate their water supplies. It is likewise our obligation to see to it that all communities have an adequate dental health program and utilize all dental health measures which will improve dental health. The *American Journal of Public Health* aptly summarizes the fluoridation program in these words, "What are we waiting for?"

Entomologists Discuss Radioactive Houseflies

The byproducts of atomic energy are now aiding entomologists in tracing the complex chemical and biological processes of insects, and also to enhance their studies of insect behavior, such as the flight range of the common housefly. Scientists of the Communicable Disease Center, Public Health Service, are using radioisotopes to mark flies for identification when later recaptured.

The housefly was described as a hobo with a cruising range of 8 miles or more, the meeting of the American Association of Economic Entomologists in Cincinnati, December 11, 1951, was told. Flight-range studies, important in measuring the insect's role in disease transmission and in planning effective control operations, were reported by Dr. H. F. Schoof, of Atlanta, Ga., R. E. Siverly, of Phoenix, Ariz., and J. A. Jensen, of Savannah, Ga., who made their experiments in Phoenix, and by K. D. Quarterman, W. Mathis, and J. W. Kilpatrick, all of Savannah, who collaborated on tests in Georgia.

For the flight-range tests, the flies are tagged with an extremely tiny amount of radioactivity, less than one finds in a radium watch dial, and so little that it is harmless to man. A counting device is used to isolate the "hot" flies upon recapture. By its use 10 radioactive flies can be isolated from 50,000 flies in less than 5 minutes.

The flight-range studies have shown: More than 80 percent of flies captured were trapped within 1 mile of the release site, thus indicating major movement in a restricted area; flies appear to move at random from any given site, being attracted by food and breeding materials, called "attractants"; and flies naturally find some areas more attractive than others, hence there is a mass movement toward those areas. Fly control programs are stressing the removal of breeding sources through sanitation. This is pointed out by the recapture in a city market of flies released in a substandard residential area where unsanitary privies were prevalent.

dependent researchers here and there and everywhere are beginning to point toward certain things which do seem to be common.

Negative Factors

It is pretty clear now that the achievement of an organization's purpose does not require all sweetness and light. Many of the writers in this field in previous generations were dubbed sweetness-and-light experts because the emphasis was on "good organization means everybody loves everybody else," and there never is any argument, never any quarreling, never any disagreement. The actual fact is, I believe, that when you get that kind of an organization, you have an organization which is dead on its feet. Only when there is honest disagreement, and sometimes fairly open conflict within an organization, does it move, grow, and develop—assuming, of course, that conflict is not carried to the point where it interferes with organizational effectiveness.

The second negative factor is that no set of personnel policies, procedures, or systems will in themselves create organizational effectiveness. We Americans love gadgets, and we love them just as much in the personnel field as we do in the kitchen. Somehow we appear to feel that if we get enough of these into a complex system, they will make for effective organization. It is not that good personnel procedures aren't important and helpful, but we can't rely on them alone to produce organizational success.

Positive Factors: Organizational Philosophy

On the positive side there are at least four general conditions of effective organization. Foremost, I would put an organizational philosophy—a way of thinking, a way of life which permeates the organization. There must, at least, be acceptance throughout the organization of its goals. There needs to be some accepted and common attitudes about the task of the organization, recognizing that the task is accomplished by and through people. Perhaps this seems trite, but it's surprising how often it is assumed somehow that if they "get out the production," that's the important thing. Effective organization demands that good human re-

lations and high production somehow be reconciled, for we accomplish everything we accomplish in an organization only through people. There needs to be, in short, a realization that the problems of human relations are everyone's job in the organization and are central to the accomplishment of the organizational purpose.

Part of this philosophy, I think, also consists of some attitudes about people—respect for the individual personality and his dignity, confidence in the potentialities of people. So often there is practically an assumption that "we in management" are elite, and that "those stupid bums" on the line maybe can get along, but they haven't anything to contribute other than what they can give with their hands and their muscles. Yet we discover over and over again, when we put it to the test, that even the lowliest worker sometimes can know more than even management about some things.

There is the example of "Big Ears" Boyer who volunteered to reconvert some large equipment in a steel plant with the aid of a plumber's helper and a little material and save the company a lot of money. When finally, through pressure from the union, he was permitted to try the experiment, he made the change at a cost of \$700 as against a bid of \$35,000 from an engineering firm. The point is simply that we tend to underestimate the capabilities and the potentialities of what we think of as the "simple" members of the mass in our society. An organizational philosophy which accounts for these potentialities, which includes genuine belief in people, is imperative to successful organizational operation.

Mutual Confidence and Trust

As a second positive condition for organizational effectiveness I would put a necessity for mutual confidence and trust between the members of the organization. Here we often assume that people who literally hate each other can somehow work effectively together in an organization. It's possible, of course, to dislike the behavior of an individual without hating him. We find, in the parent-child literature, the point stressed over and over again that you

have to love your children, but that doesn't mean you have to love everything they do.

I think the same thing is true with any type of organization relation. But when you have a face-to-face relationship with persons—just as in a family—and some of those persons literally hate each other, there is no practical way of getting organizational results. There is only one answer and that is one or the other of those has to get out. Without mutual confidence and respect, it is hardly possible to have an effective organization.

Communication That Works Both Ways

A third essential is genuine two-way communication. More and more, it's becoming apparent that communication within an organization has a great deal to do with its effectiveness and success. People need to understand what goes on, above and below. People need to have the opportunity to talk out the things that are troubling them.

Industry spends a lot of time and millions of dollars on communications devices—conference programs, letters from the President, all kinds of placards, and so on—largely to teach the workers, as they say, "the facts of economic life." This communication is, usually, strictly one way. Consequently, the dollars spent on communication are sometimes not merely wasted, but they have a negative effect, rather than a positive one. You must have communication both ways for an effective organization.

Personal Satisfaction on the Job

Finally, as a requirement of an effective organization, we return to this matter of personal satisfaction. There must be conditions which make possible what I'd like to call satisfaction on the job. It's a very interesting fact that most of the rewards which come to people in organizations are rewards which they can utilize only when they leave work. You can't spend your pay at work. The only value it has in terms of satisfaction at work has to do with whether you get more or less than somebody else. Benefits, such as insurance, recreational programs, annuities, vacations, and so on down

the list, are utilizable for personal satisfaction, in general, when you go elsewhere.

The result is that many times work becomes a kind of punishment that we undergo in order to have satisfaction elsewhere. I don't believe it's possible to have effective organization under such circumstances. I think we must find ways to make work itself a satisfying kind of experience for people. It's interesting to see how much energy people put into sports and hobbies, and plain hard work outside. It isn't a matter of getting people to work; they'll work if there's satisfaction in it. The problem is finding ways to make the work itself satisfying—to make it not a kind of punishment, but a pleasure.

Significance of Personality

Undoubtedly there are a great many other factors which influence the effectiveness of a human organization. Undoubtedly, as we go on studying and as the research piles up, different emphasis will be placed on the factors I've described, and there will be different interrelations among them. Those I have mentioned appear to me to be significant today.

Now, if you will, note that all of the things I have described are dynamic, not static. These are functional relations within an organization that change with the organization's nature and history. Where does the leader come into that setting?

Except in a very small and probably somewhat unique organization, it certainly seems that these conditions tend to be the results of the efforts of a person or persons whom we look at as the leader. Let me illustrate: Two or three years back, the National Planning Association undertook a series of case studies in about 15 industrial plants looking toward answering the question: What are the causes of industrial peace under collective bargaining? Some of these have already been published, and a final report is anticipated.

I think those of us on the research committee were convinced when we started that we would find that the effective conditions emerging from these studies had little to do with the personality of the individual who happened to be the president or the key executive in the or-

ganization. As we now analyze these studies, it is apparent that the successful situations bore no relation to the personal characteristics of the particular leaders. But one thing is very clear: In every one of those case studies, some individual, usually the president or a key member of the top executive group, seems to have been a critical factor in what happened.

The successful labor relations were not achieved independently of a person, but the personality of that individual and his particular characteristics don't seem to have been particularly significant. Size, the complexity of the organization, the difficulty of relating the purpose of the organization to the needs of the members—and I think the psychological need for a parent-symbol—all of these appear to make necessary the presence of a person who somehow coordinates, stimulates, and inter-relates the variables that we're talking about.

The Role of the Leader Is Important

So the role of the leader, as I see it, is important. Perhaps, in some circumstances, it can be shared, as in a small hobby group. Perhaps some day, with more knowledge, more skill, or with a different cultural pattern, the role of the leader can be spread through an organization to the point where the person isn't as essential as he is when we think of leadership today.

The important point I would like to stress is that it isn't the nature of the leader but the nature of the relations between organizational goals and human needs. Those essential relations are the important factors which determine the success of an organization.

In summary, understanding the nature of effective leadership is not a matter of a search for personality characteristics. More pertinent questions are: What are the conditions of organizational effectiveness . . . how does an organization achieve its purpose? When we

look in that direction—taking into account the need for willing collaboration and the need for personal satisfaction—the functional relations between those variables become the focus of attention.

Conditions of Effectiveness

Then, the conditions of organizational effectiveness—at least a few of them—are things like these: First, negatively, it doesn't require sweetness and light, and it doesn't require any particular set of systems of personnel administration. We can find, incidentally, organizations that have common patterns of personnel systems at opposite extremes in terms of the health of their human relations.

On the positive side the conditions include (a) the presence of an organizational philosophy which permeates the organization with goals that are at least accepted by the majority of the members and with certain attitudes about the task to be performed, particularly stressing the importance of the human relations side of that task, and with certain attitudes about people which take account of them as human beings with genuine potentialities, with unique personalities, and with human dignity; (b) mutual confidence among individuals within the organization; (c) genuine two-way communication; and (d) opportunities for satisfaction at work in the job situation.

Therefore, leadership to me is a set of dynamic functional relations between organizational purposes and the need for satisfaction of its members. The establishment and the coordination of those relations in most complex organizations seems to require a person, a leader. That may not be an inevitable requirement. But it is fruitless to seek a "leader type," or to seek characteristics which will be found in the effective leader regardless of the organization's conditions and of the needs of the organization's members.

Occupational Health

Beginning this month, the Public Health Service's technical magazine *Industrial Health Monthly* is being

published under the title *Occupational Health*. \$1 a year from the Superintendent of Documents.

Observations on the Epidemiology of Poliomyelitis

By W. THURBER FALES, Sc. D., and MATTHEW TABACK, A. M.

Some evidence to support the theory that poliomyelitis is spread from person to person is found in a study of the 1950 poliomyelitis epidemic in Baltimore City.

The 212 cases of paralytic poliomyelitis reported to the city health department during 1950 represent the highest annual total of reported cases ever recorded in Baltimore. The attack rate of 22.5 per 100,000 during 1950 was exceeded only once when 206 cases were reported in 1916—a rate of 33.9.

This comparatively high incidence offered material for a study of the probable mode of transmission of this disease and of its selection of specific population elements.

However, until we have reasonably accurate estimates of the incidence of newly acquired infections, conclusions drawn from a study of paralytic cases only are limited and incapable of yielding a clear definition of the epidemiology of poliomyelitis.

History of Poliomyelitis in Baltimore

Baltimore City has no record of poliomyelitis mortality or morbidity prior to 1912. Cases and case rates for each 5-year interval from 1912 to 1950 are given in table 1. Annual incidence and mortality ascribed to poliomyelitis are shown in the basic table 9. Recognition of this disease and reporting practices presumably are quite different today than they were several decades ago. Since 1934, when non-

paralytic cases were specifically excluded, extreme annual variations in incidence have occurred. The number of cases have varied from 3 to 212 and the case rates, from 0.32 to 22.5 per 100,000 population. No clear-cut time sequence can be developed on an annual basis. When attack rates are considered for white and Negro segments of the population, reported

² Not available.

morbidity among Negroes is consistently, but not markedly, lower than that recorded for white persons.

The epidemic of 1950 was preceded by a 5-year period of comparatively constant incidence. The average annual number of cases was 34, and the corresponding rate was 3.6 per 100,000. During this period, the case fatality ratio was 8.9 percent. Previous years of high incidence were 1944 and 1941. It is essential to recall also that the extraordinarily high birth rates from 1945 to 1949 added to the population approximately 100,000 young children—10 percent of the entire population.

Dr. Fales is director of the statistical section and Mr. Taback is director of the bureau of biostatistics, Baltimore City Health Department.

Epidemic of 1950

Distribution of paralytic cases reported for 1950 according to week of onset shows September 3 as the median point for the whole population (table 2 and fig. 1). There is remarkable uniformity in the curves for white and Negro segments. The median points are September 6 and August 29, respectively.

The range of the curve for the total population extends from July 1 to November 16. If consideration is confined to the weeks of excessive incidence,¹ the epidemic range extends from approximately July 29 to October 19, a period

¹ Median weekly frequencies based upon experience during 1945-49 were used to determine the interval during which poliomyelitis was present at above-average levels.

of 12 weeks. Thus, the hypothesis of a common source single-exposure epidemic is inconsistent with the distribution of cases by time of onset of disease, since the epidemic course extended beyond 35 days (1)—the extreme estimate of the incubation period for poliomyelitis.

It is the practice of the bureau of biostatistics in Baltimore to spot cases of poliomyelitis on a city census tract map according to the residence of the patient. During the 1950 epidemic, there was a gradual movement from the hub of the city to the periphery in the time sequence in which cases were reported. This movement is shown in a series of spot maps in figure 2 and summarized in table 3.

Figure 1. Reported cases of paralytic poliomyelitis by week of onset and population segment, Baltimore City, 1950.

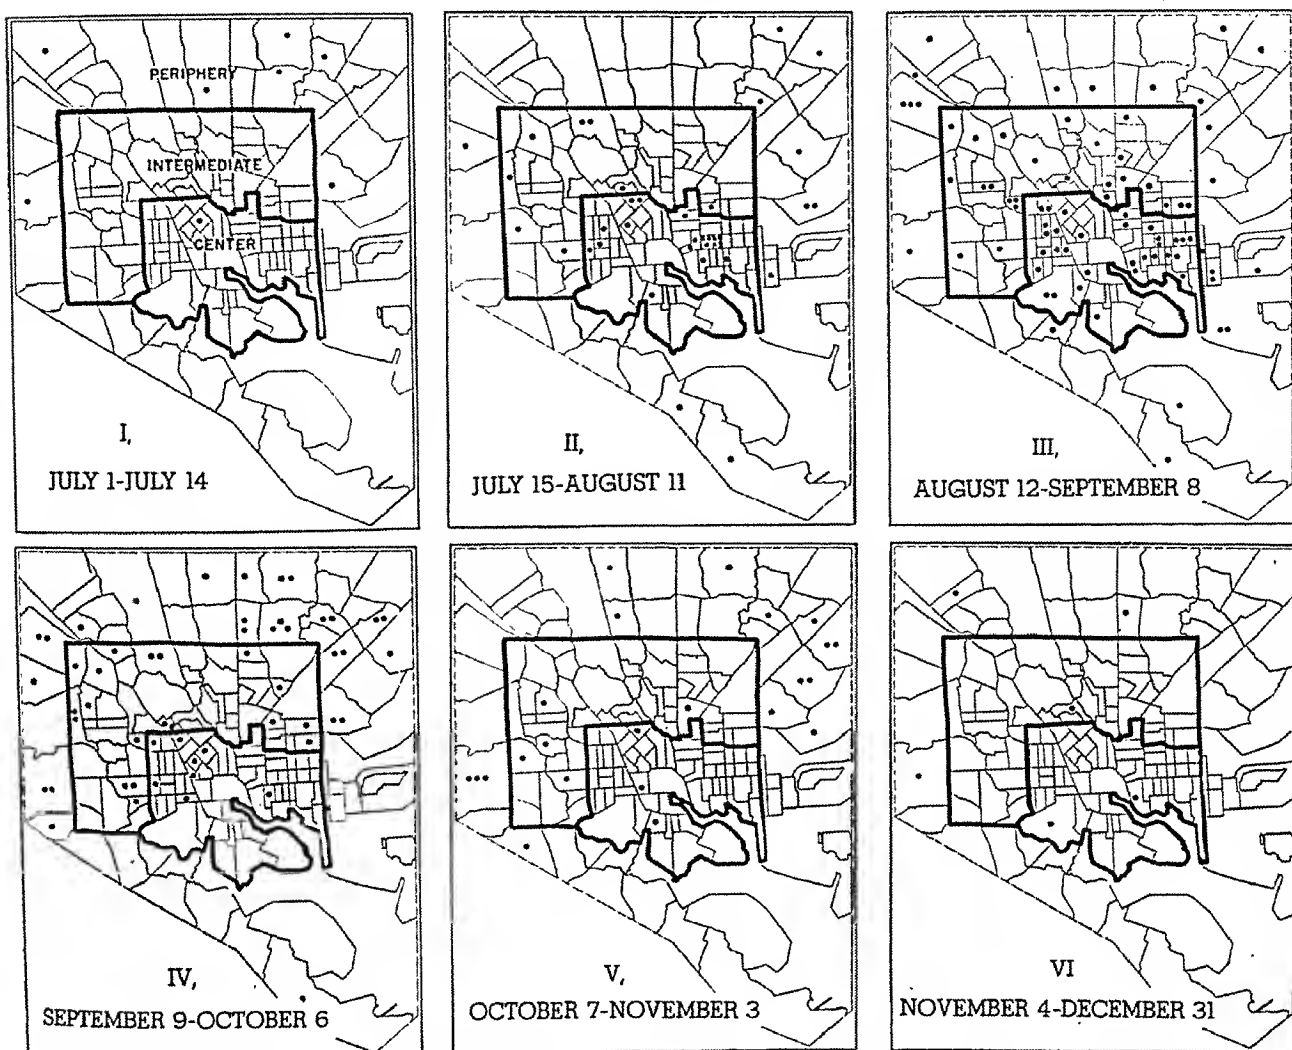

The median date of onset, a convenient index of central tendency, falls on August 25 for the cases in the center of the city. It was 3 weeks later (September 15) before the median case was attacked in the periphery of the city. A test of this difference indicates the improbability that it was caused by chance. The observation of a significant time differential in the case distribution for specified city areas makes it extremely unlikely that the disease process was associated with exposure to a common source.

Mode of Transmission

Having rejected a common source as a probable mode of transmission, is there any evidence which would be consistent with a hypothesis that poliomyelitis is a propagated epidemic?

An analysis of the spot maps in figure 2 indicates the presence of a sporadic distribution of cases throughout the city during the early phase of the epidemic period. However, one

Figure 2. Cases of paralytic poliomyelitis according to broad city zones and date of onset, Baltimore City, 1950.

then observes a variable rate of progress in specified zones. The most rapid spread in time occurred in the central area of the city and the slowest development, in the peripheral zone.

The data presented on time differentials in

the progress of the epidemic in selected city zones is explainable by the logical thesis that opportunities for interpersonal contact are somewhat less in the peripheral areas as compared with the central zone of the city. It

Further support for the person-to-person contact basis for transmission of poliomyelitis is given by Turner and his associates (2) in a study on the age incidence of infection by Lansing poliomyelitis virus. These investigators, working with the Lansing strain of polio-

¹ Beginning with 1935 nonparalytic cases have been specifically excluded.

diseases whose transmission appears to be based on a person-to-person contact principle. As indicated later several other characteristics of poliomyelitis appear to be consistent with this mode of transmission.

Age Selection in Successive Decades

In table 5, attack rates by broad age groups are shown for three periods centered about a year of the decennial census. As an aid in sensing age selection, table 6 presents the age specific rates for each age period as percentages of the rate for 0-4 years.

During three decades, the tendency has been toward a greater selection of older age groups for attack. This, we feel, is entirely consistent with a thesis of person-to-person contact. Proportionately, during the past 30 years the percentage of population residing in densely populated areas has declined and family units have become smaller. There has also been a tendency toward reduction of the probability of interpersonal contact, particularly at school and preschool ages. This in turn has led to a retardation in the exposure of new susceptibles to poliomyelitis infection.

Negro Rates Lower

During the 10-year interval 1940 to 1949, the annual attack rate among Negroes has averaged 2.7 per 100,000 as compared with the white attack rate of 5.4.

Turner and associates (2) indicate an earlier exposure in Negroes than in white residents to Lansing poliomyelitis, and this is substantiated by recorded attack rates for 1950 (table 7). Since early exposure appears to result in a milder form of disease (table 8) there is reason to believe that the lower Negro morbidity rates for poliomyelitis are a reflection of earlier exposure, not of less exposure, which is entirely consistent with a person-to-person concept of transmission.

Seasonal Character

With very few exceptions from 1912 to 1950, poliomyelitis has originated in early summer, reached a peak in September, and terminated in November or December (table 9). The seasonal distribution of poliomyelitis is one of the attributes of the disease which is difficult to explain solely on the person-to-person mode of transmission. This characteristic is one of the principal elements in the epidemiology of poliomyelitis which awaits clarification. There exists perhaps a virulence or growth factor in the poliomyelitis agent which is seasonal in variation, but this remains to be demonstrated experimentally. Variation in host factors is

another possible explanation awaiting further investigation.

Summary

1. Consideration of the distribution of cases according to white and Negro persons and geographic areas during the 1950 poliomyelitis epidemic in Baltimore City has led to a rejection of the hypothesis that the epidemic could have been caused by a common source vehicle.

2. Evidence for regarding poliomyelitis as a propagated disease of the person-to-person type has been presented.

3. Selection for attack of older groups in higher socioeconomic levels has been demonstrated to be consistent with the hypothesis of regarding poliomyelitis as a disease propagated by interpersonal contact.

Trichophyton tonsurans Ringworm— A New Public Health Problem

By LUCILLE K. GEORG, Ph. D.

Ringworm infections due to *Trichophyton tonsurans* are becoming an increasingly important public health problem in the United States. Isolations of this fungus from clinical cases of ringworm of the scalp, as well as from ringworm of the glabrous skin and nails, are made more frequently than heretofore in certain sections of the country, especially in Texas and other southwestern States.

Clinical Aspects

Scalp lesions are usually superficial and chronic; the infections can persist for years. The irregular bald patches produced may be small and interspersed with normal hairs (figs. 1 and 2). The indistinct appearance of the lesions, as well as the fact that trichophyton-infected hairs fluoresce very little, or not at all, under the Wood's lamp, makes their detection extremely difficult. Many cases have been mistakenly diagnosed as dandruff or psoriasis (1). In a small percentage of cases, the lesions are more widespread and are characterized by the development of inflammation and even kerion (2).

Hair infections due to *T. tonsurans* are characterized by endothrix parasitism. In scalp lesions, the organism is found almost exclusively within the hair, the spores being arranged in chains (fig. 3). The infected hairs are thickened and darkened by the mass of fungus spores within them. They tend to break off at the surface of the scalp, leaving smooth bald areas with dark hair stumps em-

bedded in the superficial scales (fig. 2). This gives the area a speckled, "black dot" appearance which is very striking in some cases. Lesions of the glabrous skin and nails are indistinguishable from ringworm produced by other *Trichophyton* species.

Infections due to *T. tonsurans* apparently are always derived from human sources, and it is difficult to infect an experimental animal. Although the majority of scalp lesions occur in children, the infection does not, as in microsporiasis, tend to disappear at puberty but may persist into adult life. Infections are usually not epidemic but they may spread to all members of a family (1). Scalp lesions are, in general, refractory to conservative treatment, and roentgen ray epilation is considered the treatment of choice.

Laboratory Diagnosis

Diagnosis is based on direct examination of NaOH preparations of the hair stumps, removed with a fine forceps or the point of a scalpel, or of scrapings from lesions of the skin or nails. The position of the fungus mycelium and chains of spores packed within the hair is evidence of infection by an endothrix trichophyton. In order to observe the true position of the fungus, the outer walls of the hair should not be damaged. Therefore, care must be taken not to crush the preparation or to apply excess heat in clearing it. Only two recognized dermatophyte species found in the United States produce this picture in the hair, *T. tonsurans* and *T. violaceum*. The latter species is extremely rare and its colonial characteristics allow it to be readily differentiated from *T. tonsurans* (3). NaOH mounts of skin and nail

Figure 2. Close-up of a lesion showing "black-dot" appearance.

scrapings reveal mycelia and arthrospores which are indistinguishable from those of any of the ringworm fungi.

Only by culture of the infected hairs, skin, or nail scrapings can the identity of the etiological agent be determined. *T. tonsurans* grows readily on Sabouraud's dextrose agar, producing a colony which is characteristically heaped and folded in various patterns. The surface is usually finely powdery and may show a wide range of pigmentation from white to tan, or shades of rose, violet, or yellow. One variety, which is particularly common in this country, has sulfur-yellow pigment and is known as the variety *sulfureum*.

Microscopic observation shows long, septate hyphae that are often highly irregular and varying in thickness. Some of the thick mycelium may have a knobby surface. Microconidia are numerous in the powdery surface growth of the colony, appearing as large pyriform or elongate spores that develop along the sides of the mycelium or in loose clusters. They are extremely variable in size and shape and in some instances are two-celled or appear to be budding. Macroconidia are only occasionally found and are thin-walled, slightly clavate or club-shaped, abortive structures usually of only two or three cells. Old cultures show masses of chlamydospores.

The literature lists *T. tonsurans* under many names in the "crateriform group of the endothrix trichophytions." The most common syno-

nymy are: *T. crateriforme*, *T. sulfureum*, *T. acuminatum*, *T. epilans*, and *T. sabouraudi*. According to Carrión and Silva (4) and González Ochoa and Romo Vázquez (5), it seems logical to consider these as colonial variants of the single species *T. tonsurans*, since the differences are based only on general colony form and pigmentation. Colony form, particularly the manner of the surface foldings, and pigmentation are highly variable within any of the single dermatophyte species. Figure 5 shows four common colonial variations of *T. tonsurans*.

Epidemiology

For the past 8 to 10 years, the common agent of ringworm of the scalp in the United States has been *Microsporum audouinii*, and this organism has been responsible for widespread epidemics in many communities. In some sections of the country it is the cause of 80 to 90 percent of the cases of ringworm of the scalp (6). In Mexico and Puerto Rico, however, *M. audouinii* infections are rarely seen, and a large percentage of the cases are due to the endothrix fungus, *T. tonsurans*. In a survey of cases of ringworm of the scalp in Puerto Rico, Carrión and Silva (4) reported that 15 of 35 cases seen over a period of 11 years, or 40 percent, were due to *T. tonsurans*. No cases of infection due to *M. audouinii* were reported. González Ochoa and Romo Vázquez (5) have described 268 cases of ringworm of the scalp from Mexico. They

ascribed 89.4 percent to *T. tonsurans* and none to *M. audouinii*.

T. tonsurans infections have been thought rare in most sections of the United States. A number of cases have been reported from several of the eastern port cities, particularly New York City, but here the percentage of tinea capitis cases caused by *T. tonsurans* was never high. Lewis and Hopper (3) reported only 13 from a series of 748 cases seen over a period of 6 years, or approximately 1.7 percent. Montgomery, Heinlein, and Karpluk (7) listed only 0.2 percent in a series of 2,857 cases of tinea capitis seen over a period of 7 years, and Benham (8) cited 0.8 percent in a series of 677 cases seen from June 1949 to June 1950. My personal observations of cases of *T. tonsurans* infections seen at Vanderbilt Clinic, New York City, indicated that these infections commonly occurred among Puerto Ricans who had recently immigrated to the United States. Scattered cases have been reported from Illinois (9), Pennsylvania (1), Massachusetts (10), Tennessee (11), Michigan (12), a case with lesions of the smooth skin only, Minnesota (6), Missouri (2), Oklahoma (13), and Cali-

Figure 3. Hair showing endothrix invasion.

fornia (14), and recently the mycology laboratory of the Communicable Diseases Center has received cultures of *T. tonsurans* for identification from Indiana, Iowa, Massachusetts, Virginia, and Canada.

In contrast to these occasional isolations, relatively large numbers of cases have been reported

from Texas, and the number of cases has been increasing in the past few years. Lehmann and Pipkin first isolated *T. tonsurans* from the San Antonio area in 1927. In 1936 and 1937, these authors, in collaboration with Emmons, conducted an extensive survey of tinea capitis in this locale. At that time, approximately 13 percent of the cases seen were proved by culture to be due to this fungus (15). Pipkin, in a recent

Figure 4. Microscopic mount from a culture of *T. tonsurans* showing morphologic variation of microconidia and two abortive macroconidia.

communication, states that since this time he has seen constantly increasing numbers of cases of ringworm due to *T. tonsurans*. From 1947 through the first 9 months of 1951, he and his co-workers observed 592 cases of tinea capitis. Of these, 120, or 20.3 percent, were caused by *T. tonsurans*. Many of these cases of ringworm of the scalp recorded from Texas have been in adults. Of 57 cases of ringworm of the scalp in patients past puberty reported by Pipkin (16)—39 in adults and 18 in adolescents—42 cases were due to *T. tonsurans*. Seale (17), of Houston, also reports having seen a high percentage of ringworm cases caused by this fungus. Of 153 cases seen over a 2½-year period, 31, or 20.6 percent, were caused by *T. tonsurans*. He states, "There is no doubt that *T. tonsurans* infections are on the increase in this area."

Recently Livingood (18), of Galveston, has furnished us with statistics on the number of cases of *T. tonsurans* infections he has observed

Figure 5. Colony variants of *Trichophyton tonsurans* on Sabouraud's dextrose agar. A. Variety *acuminatum*; B. variety *sulfureum*; C. variety *crateriforme*; D. variety *cerebriforme*.

in Galveston county. Of 82 patients who had tinea capitis, 56, or 68 percent, were due to this organism. Of these patients 44 were Latin-Americans. Livingood and Walton (19) have

begun a careful survey of the schools of Galveston county, and their preliminary findings suggest that *T. tonsurans* infections are not uncommon in the school children, especially in Negroes and Latin-Americans. In a Negro school in the city of Galveston, four cases were found among 146 children. In other schools in Galveston where both Latin-American and Anglo-American children attend, the percentage infected with *T. tonsurans* was considerably less. Eight cases were seen among 790 children examined. In this school survey, the children infected were either Negroes or Latin-Americans, with one single exception.

Since Mexico is an endemic area for *T. tonsurans* infections (5), it seems probable that the disease has been spreading into Texas and the southwestern States from this area. It is possible that *T. tonsurans* may produce a widespread epidemic in the school children in the United States in a fashion similar to that of epidemic ringworm due to *M. audouini*. The problem would be more difficult, however, because the infections occur in both children and adults. They are more difficult to detect and usually are more refractory to treatment.

Aquatic Invertebrates as Indicators Of Stream Pollution

By ARDEN R. GAUFIN, Ph. D., and CLARENCE M. TARZWELL, Ph. D.

Year-round field studies of the biology of stream sanitation were initiated by the biology section of the Public Health Service's Environmental Health Center on Lytle Creek in October 1949. The aims of these investigations were:

1. To develop or devise and field test procedures and equipment for biological surveys and investigations of polluted streams.

2. To investigate seasonal and diurnal environmental changes in a stream polluted with oxygen-depleting wastes.

3. To determine how the physical-chemical environment in the various pollutional zones affects the qualitative and quantitative composition of aquatic populations and how these populations in turn affect or change physical-chemical conditions.

4. To relate various qualitative and quantitative compositions of aquatic populations to environmental conditions found in streams polluted with organic wastes and to test the value and use of aquatic organisms as indicators of clean water and various degrees of pollution at all seasons of the year.

5. To determine the rate of satisfaction of biochemical oxygen demand (BOD), the area in which most of the demand is satisfied, and how seasonal and other environmental conditions affect the process.

6. To determine the value of fishes as indicators of pollution and their use in evaluating the effects of pollution.

The composition of the aquatic fauna in

various sections of the stream and diurnal changes in environmental conditions are discussed here.

Lytle Creek, which was especially selected for the study, is about 45 miles northeast of Cincinnati, Ohio, and is a tributary of Todds Fork, a part of the Little Miami River system. It is a small stream approximately 11 miles long, 3 to 35 feet wide during non-floodstage, and a few inches up to 6 feet deep. The principal natural source of water in the stream is surface drainage from the surrounding area. Some 7 miles above its mouth, the creek receives the effluent from the primary sewage treatment plant of Wilmington, Ohio, a city of about 10,000 people. Lytle Creek is particularly favorable for studies of the pollutional effects of oxygen-depleting wastes because it has only one source and type of pollution (domestic wastes from Wilmington); it has no permanent tributaries below the source of pollution; and it has all degrees of pollution from a definite septic zone through recovery and back to clean water.¹

Procedures

One of the early objectives of the Lytle Creek investigations was to evaluate the reliability and possible use of aquatic organisms (chiefly benthic forms) as indicators of the extent and severity of pollution and the degree of stream recovery. Plans were made for a comprehensive

Dr. Tarzwell is chief and Dr. Gaufin is biologist of the biology section of the Public Health Service Environmental Health Center, Cincinnati, Ohio.

¹ Zones of pollution, as herein considered for Lytle Creek, are based principally on the amount of dissolved oxygen occurring throughout the stream. The septic zone is the area of stream showing oxygen depletion during at least some portion of the year. It grades gradually into the recovery zone where the minimum oxygen concentrations range from 0.1 to 2 ppm. In the clean-water zone minimal oxygen concentrations may be as low as 2 ppm for short periods of time.

sive study. A detailed survey was made of the stream and a map prepared showing the location and extent of pools, runs, and riffles, and the stream profile and gradient. A sharp crested rectangular contracted weir and continuous float level recorder were placed in the stream about 3 miles above its mouth for the continuous recording of flows.

During the winter and spring, flows average about 6 to 7 cubic feet per second (cfs) with frequent floods of 40 cfs or more. In late summer and fall, flows are generally small, about 0.1 cfs above the sewage plant outfall and 1 cfs below it. During periods of low summer flow, the sewage plant effluent overwhelms the stream with oxygen-depleting wastes and causes a septic zone to be produced immediately below the outfall.

Ten stations were selected along the stream course for periodic sampling in all zones. These stations were designated by their distance in miles upstream from the mouth, as stations: 0, 1, 2.8, 4.2, 5.2, 6.5, 7.2, 7.3 (sewage outfall), 7.6, and 8.7. Monthly, or more frequently, samples were taken at these stations for the determination of dissolved oxygen, pH, CO₂, methyl orange, and phenolphthalein alkalinity, and temperatures. Quantitative bottom samples were taken at monthly intervals at each station in pools, runs, and riffles. A Surber square-foot sampler was used in riffle areas, while a Petersen or Ekman dredge was used in other areas. Marginal samples were also taken, and reconnaissance surveys of bottom and surface fauna were made along the entire stream. (BOD studies have been made periodically at all stations, as well as plankton, microbottom fauna, and fish population studies.)

In the Lytle Creek investigations emphasis was placed on year-round studies to determine seasonal variations in aquatic populations and ecologic conditions. Attention was also directed to diurnal variations in physical and chemical conditions, especially during the spring and summer when they are more pronounced. Physical-chemical variations were determined by taking hourly samples at each of the stations for a 24-hour period. By these and other studies, information was obtained concerning ecologic conditions and their diurnal and seasonal variations in each of the zones.

These data were then correlated with those obtained by the quantitative and qualitative studies of the benthic, marginal, and surface

Range in dissolved oxygen, Lytle Creek, August 22-23, 1951.

fauna to provide information on (a) aquatic populations which can be expected to develop under certain ecologic conditions, and conversely (b) environmental conditions or variations in environmental conditions which are indicated by various compositions and densities of aquatic organisms.

Results

The chemical and physical data collected during 6 sampling runs for the 10 stations are enumerated in table 1. These data present the maximum and minimum oxygen concentrations and water temperatures occurring in the stream during the early spring and summer months. Since a wide difference in the amounts of oxygen present in the stream during day and night was noted, special attention was paid to hourly variations in the dissolved oxygen content. The range of these variations for the period 9:00 a. m. August 22 to 8:00 a. m. August 23 is presented in the chart. During the reconnaissance surveys, conducted in connec-

tion with the sampling runs, 68 genera and 79 species of animals were collected and identified. Of these species, 29 percent were Diptera, or fly larvae, a group which is adapted to live under a wide variety of environmental conditions. Fifteen species of organisms were taken in the septic zone, but only six of them, *Chironomus tentans*, *Culex pipiens*, *Eristalis* sp., *Physa integra*, *Limnodrilus* sp., and *Tubifex*

sp., were abundant. Of the 23 species of mayflies, stoneflies, and caddisflies taken, only one species, *Callibaetis* sp., occurred outside of the clean-water zone. The organisms collected at five stations representative of each of the zones are listed in table 2. Their comparative abundance by month and zone is also indicated.

Among the primary requisites for animal existence are oxygen and food. When estab-

lishing biological indices of pollution, such requisites must be taken into consideration. In Lytle Creek from November 15, 1950, to April 1, 1951, the volume of flow was more than 6 cfs on all except three occasions. The time of flow from the sewage outfall to the mouth at Todds Fork never exceeded 48 hours. Water temperatures were under 60° F., and oxygen concentrations approached saturation throughout the

stream. From the standpoint of dissolved oxygen, the stream was satisfactory for most types of bottom organisms throughout its length during the entire period. Chemically, the water appeared to be relatively free from harmful pollution, but the fauna that was present still reflected the critically low oxygen concentrations occurring in the past.

From April 1 to October 1, the volume of flow

dropped to an average of 1 cfs, the time of flow extended to 7 or 8 days, water temperatures rose to as high as 87° F., and oxygen concentrations became critically low in the 4-mile section of stream below the sewage treatment plant outfall. Definite pollutional zones were established in May and persisted throughout the summer. An abundant food supply and a variable oxygen supply below the treatment plant outfall resulted in a distinctive fauna in each of these zones.

Critically low oxygen concentrations were found in the stream during the night at station 6.5 as early as May 9. Concomitant with the low nocturnal values, remarkably high oxygen concentrations were recorded during the afternoon at the same station. Peak concentrations of oxygen for the season occurred before the deciduous stream-side trees began to exercise a shading influence. A dissolved oxygen value of 19.4 ppm was found at station 5.2 at 3 p. m. on May 9. This peak was produced by a heavy plankton bloom. When marginal vegetation shaded the stream, blooms became less marked and daytime oxygen values were not as high.

As the summer advanced, oxygen depletion became of progressively greater duration and extent. The result was a well-defined oxygenless zone extending from the sewage treatment plant outfall to a point 2 miles downstream, as indicated by studies carried out on the night of August 22. This depletion persisted throughout the day at stations 7.2 and 6.5. The range in hourly dissolved oxygen values found late in August at the various sampling stations along the stream is shown in the chart.

Discussion

One of the primary objectives of the Lytle Creek studies has been to arrive at a better definition of indicator organisms. The finding of certain organisms, such as rat-tail maggots, *Eristalis* sp.; sludgeworms, *Tubifex tubifex*; and bloodworms, *Chironamus tentans*, presents important evidence of the pollutional condition of a stream (1), while the absence of cleaner water forms is likewise a valuable measure of existing conditions.

With favorable ecologic conditions, such as high temperatures, uniform flow, freedom from

floods, and abundant food, prevailing throughout the summer of 1951, a surprisingly large and varied macrobottom fauna developed in the stream. This condition was observed during May and again in August when special collections of aquatic organisms were made at all sampling points along the stream, and their distribution correlated with the diurnal physical and chemical conditions prevailing at the various stations.

In evaluating aquatic organisms as indicators of pollutional conditions, great caution must be used because of several complicating ecologic conditions. First, many organisms which occur in large numbers in extremely polluted water may also be found in limited numbers in cleaner situations. Several species of invertebrates, such as the mosquito, *Culex pipiens*; beetle, *Tropisternus* sp.; and sludgeworms, *Limnodrilus* and *Tubifex* spp., which occurred in abundance at stations 6.5 and 5.2, also occurred in the clean-water zones. Second, many species listed in table 2 occurred in such small numbers as to discourage their individual use as indicators. Third, several ecologic factors other than the presence of a pollutant may limit the distribution of certain species; for example, erosion, floods, the size of the stream, the type of bottom, the flight range of the insect, and the portion of the stream under study. It is believed that the moderate abundance of single species should not be considered as biological indicators of pollution because organisms such as *Tubifex* usually associated with polluted areas are also found in clean waters. It is the complex or association of organisms which is important for indicating clean or polluted water. All organisms present and their relative abundance must be considered.

In satisfactorily using associations of aquatic organisms as indicators of pollution, the absence or much reduced numbers of formerly present clean-water species in an area may be as important, or more so, as numbers of known pollutional forms (2). In this connection, table 2 shows that such insects as mayflies, caddisflies, stoneflies, and hellgramites were almost entirely limited to the clean water occurring at stations 8.7 and 2.8. The only exception was a mayfly, *Callibaetis* sp. This form was collected in a marginal surface sample and evidently had

been able to obtain sufficient oxygen from the surface film to survive.

The absence of organisms, which are indicative of clean-water conditions, from a section of stream should not always be taken as definite indication of pollution. A knowledge of the life histories of the various groups of aquatic insects often is helpful in interpreting the meaning of their distribution. For example, in the collection of invertebrates made in August, only one species of stonefly and five species of caddisflies were represented. In the May collection five species of stoneflies and nine species of caddisflies were present. Their absence later on was due to their emergence as adults during the intervening months. Similarly, the absence of some beetles, dragonflies, and damselflies in the earlier collections was partly due to their presence in immature stages so that they were missed or overlooked.

Apart from the fact that pollutional organisms must be found and clean-water species must be missing in delineating the zones of pollution in a stream, the mode of occurrence of the organisms must be taken into account (3). For example, the assemblage of organisms found in the polluted zones of Lytle Creek presented the following characteristics: (a) very large numbers of individuals; (b) few species represented in the fauna; (c) principally scavenger types present; and (d) the presence of forms having low oxygen requirements or special adaptations for obtaining their oxygen supply. Not over 10 different species of macroinvertebrates were taken from stations 6.5 and 5.2 in the septic zone at any one time, while as many as 40 species were found in the clean-water zones (table 2). However, as many as 3,000 *Culex pipiens* or 20,000 Tubificids were collected per square foot sample in the septic zone, while no species exceeded 500 individuals per square foot in the clean-water area. All the insects occurring in the septic zone have special adaptations for obtaining oxygen, such as the caudal respiratory tubes of the mosquito and rattail maggot or the air space under the elytra of the beetles. With such adaptations, depletion of oxygen in the water does not serve as a barrier to their distribution. An abundant food supply enables

these forms to attain a great abundance in polluted areas.

When conditions are favorable for organisms which can adapt to pollution, they thrive and build high populations (4). For this reason, the society of organisms found in zones of pollution is highly significant in offering clues to the intensity of pollution and the degree of recovery. If changing conditions brought about by pollution are unfavorable, organisms must resist these changes, migrate, or be destroyed. Since many of the species of insects found in Lytle Creek are found in both the lower and upper sections of the stream but are missing in the pollutional zones, and since such organisms are continuous in other nonpolluted streams in the area, it seems probable that pollution is responsible for their discontinuous distribution in Lytle Creek.

In a stream polluted with organic wastes, a certain reduction of the supply of dissolved oxygen may occur in a certain section throughout the year, during the summer months, or for only a few days in the year. Because pollution surveys frequently cannot be made during the period of critical conditions, and chemical studies give information on physical-chemical conditions only at the time of sampling, there is need for additional methods which can be used throughout the year for determining over-all conditions and the extent and severity of brief critical or limiting environmental factors. The qualitative and quantitative composition of an aquatic population is determined by recurring critical conditions, even though of short duration, as well as the more stable or long-time environmental factors. Therefore, the complex of organisms which develops in a given area is in turn indicative of environmental conditions which have occurred during its development. Organisms having life histories of a year or more will thus serve to indicate unfavorable or limiting conditions that have occurred several months previously. Because aquatic populations are a result of past environmental conditions, they serve as a means for determining such conditions in a stream. They are especially valuable because they can be used during fall, winter, or spring months, when flows are large, dilution is at a maximum, dissolved oxy-

gen is near saturation, and visual evidence of pollution at a minimum, to delineate former septic areas or to indicate critical conditions of short duration.

In order to utilize aquatic populations in this way, however, it is essential to have a knowledge of the species composition and abundance of the various organisms in the population under the various ecologic conditions which prevail in clean and in polluted waters. Further, consideration must be given to the fact that pollution with organic wastes is only one of the several environmental factors determining the composition of aquatic populations. Other environmental factors, such as type, size and character of the stream, variations in flow, severity of silting, floods and erosion, water temperatures and the character of the watershed, are all important in determining the make-up of aquatic populations. Occasionally, there is a sparsity of bottom organisms which makes the drawing of any conclusions in regard to organic pollution difficult. However, one who has knowledge of and experience with aquatic organisms can, by a reconnaissance survey, learn a great deal about the severity and extent of pollution and the extent of stream recovery even though the survey is made at a time of year when the physical-chemical indicators of pollution are least evident or largely absent.

Conclusions

1. Single species of organisms such as *Tubifex tubifex*, or *Chironomus tentans* cannot be used safely as indicators of pollution unless their relative abundance is considered.

2. The absence or much reduced numbers of formerly present clean-water species constitutes an important index in evaluating the degree of pollution.

3. The quantitative and qualitative composition of an aquatic population constitutes a valu-

able index in delineating zones of pollution in a stream.

4. In interpreting the distribution of organisms in a stream as an index of pollutional conditions, all environmental factors should be considered.

5. Pollutional associations are characterized by few species but large numbers of individuals.

6. The association of organisms normally present under most septic conditions is characterized by the absence of plant and animal eaters and the presence of scavengers.

7. Organisms characteristic of septic zones are those which can exist under conditions of very low oxygen or have adaptations for breathing atmospheric oxygen.

8. Nocturnal deficiencies in dissolved oxygen are often the critical environmental factor which determines the distribution of organisms in a stream.

9. Under conditions of organic pollution diurnal-nocturnal deficiencies in oxygen are sometimes concomitant with supersaturation of dissolved oxygen.

ACKNOWLEDGMENTS

An investigation of this type requires the services of a considerable number of people. The entire staff of the biology section has assisted in certain phases of the study, and their contributions are acknowledged. The authors express their appreciation for extensive assistance to Dr. C. M. Palmer, George Paine, Harold Walter, Jack Hammond, Dr. Max Katz, and Thomas Maloney.

Health Departments and the Housing Problem

By RALPH J. JOHNSON, M. S.

Despite advancing standards of living, 16,000,000 American families live in housing that has basic health deficiencies. This is the hard core of the housing problem for health officials; it is a problem that they can help to reduce.

The housing problem is pervasive; every individual, group, and organization has a stake in attacking it. Unless positive action is taken,

Mr. Johnson is a member of the Joint Committee on Housing and Health of the American Public Health Association and the National Association of Housing Officials, and has been active in the American Standards Association and other groups. He is senior sanitary engineer with the Public Health Service's Division of Engineering Resources.

this problem can only increase. The housing situation is not static. Heavy outlays of housing goods and services are necessary merely to provide for the population increase, for normal maintenance, and to offset obsolescence. Far heavier outlays are necessary to improve the relative supply of decent housing. These are the relentless dynamics of housing progress.

The attack on housing conditions through new construction, redevelopment, and public housing has been described extensively. But the opportunities for improving substandard housing by enforcement of health regulations has been given far too little attention.

The health department has a unique and personal relationship with the families who occupy substandard housing. The public health nurse and sanitarian are frequent visitors to the slum home and the blighted area. Morbidity and

mortality rates, along with nuisance complaints, are almost always higher in these areas than the average for the community. It follows that public health problems are greater and expenditures for services higher in these areas.

The housing problem is not hopeless—even the root-evil of poverty is not entirely insurmountable. An attitude of despair and neglect is the precise prescription for decay and rot which is the forerunner of the creeping blight that turns decent housing and its environment into slums. It is undeniable that there is a reciprocal effect between physical conditions of blight and family morale. Tenant and owner neglect of dwellings and community neglect of environment and services interact upon and contribute to each other. Somewhere in every slum is to be found a combination of these factors.

This regressive trend can be reversed. Many changes and improvements can be made within existing knowledge and ability. The problem becomes in part, then, a matter of attitude. Health officials are in a strategic position to stimulate a new attitude of confidence in our capacity as a Nation for positive improvement of much of our present substandard housing.

It has been demonstrated in several cities that when health departments enforce minimum standards of healthful housing, community interest is awakened and incentive for further improvements is provided. In true American fashion, neighbors begin to help each other and themselves; they paint the porches, repair the walls, clean the yards, mend or remove fences, and plant flowers. Departments of city government repair streets, provide better garbage collection, remove dead tree limbs, and improve services. An act of magic has not been performed, but self-respect has been restored in a deteriorated environment. The trend has been reversed; positive forces—which, like negative forces, interact and augment each other—have been put to work. When these forces become dominant, fundamental mastery of the problem has begun.

However, no single neighborhood, nor single office of government, branch of industry, or organization of citizens can alone master the total problem. A single agency or organiza-

tion can no more expect to solve the whole housing problem than can a single agency or organization expect to deal effectively with any other major problem of society.

The Housing Problem

Housing problems are as complex as the world we live in—the resultant of a multitude of interrelated and interdependent forces. They are functions of such fundamental factors as natural resources, land, population, income, labor, industry, government, war, and peace. For at least a century in this country, we have had the housing problems of high land density, intermixture of land use, inadequate planning, overcrowding, and poverty (1,2). Housing, in other words, cuts across social, political, and economic boundaries.

The entire housing problem also is related to transportation, community expansion, interest rates—in short, a whole complex of factors other than the dwelling and its immediate environment. We are concerned here mainly with substandard housing and its relation to public health. We may measure an important dimension of this problem by studying the numbers and types of substandard housing as revealed by the 1950 census (3).

Notwithstanding the greatest building boom in our history, approximately one-third of the Nation's 46,000,000 dwellings have basic health deficiencies. Approximately 6,600,000 dwelling units—1 out of every 7 in the country—are overcrowded. About 1 out of 11 dwellings is so dilapidated that it provides inadequate shelter or protection against the elements or actually endangers the safety of the occupants. Approximately 13,800,000 dwellings—almost 1 out of 3—lack hot and cold running water inside the structure. More than 6,900,000 have no piped running water. Only half of these are in rural farm areas.

Approximately 12,900,000 dwellings lack decent toilet facilities. Surprising as it may seem, only about one-third of these deficiencies are in rural farm areas. Almost 1 out of 3 dwellings do not have bath facilities or the occupants must share these facilities with some other family. More than 1 out of 4 dwellings do not have a bathtub or shower and more than 60 percent

... at least $\frac{1}{3}$ of the nation's 46,000,000 dwellings have one or more
BASIC HEALTH DEFICIENCIES

● Overcrowding

● No decent toilet facilities

● Inadequate bath facilities

● Unsafe water supply

● Poor light and ventilation

● No electricity

● No hot and cold running water

● Dilapidation

● Poor heating—open gas burners

● No dual egress

of these are found in urban and rural nonfarm areas.

The division between substandard and acceptable housing is shadowy and covers a range of units. However, using "condition and plumbing facilities" as an indicator, it can be estimated from the 1950 census of housing that approximately 16,000,000 dwelling units have one or more basic health deficiencies. Detailed surveys by local health departments in representative communities across the Nation underline these national figures.

If we consider the needs revealed by these figures along with the modern concept of health as a condition, not only where disease is absent, but where there exists the desire and ability for productive effort in concert with family and community, then the health department's opportunities and responsibilities emerge in their true perspective.

As new housing production declines (4), the health department's role in relieving the hous-

ing problem becomes the more urgent. The supply of good housing can be increased by rehabilitating existing substandard housing which has a sound frame and foundation.

Methods of Attacking the Housing Problem

With some simplification, the attack on the housing problem in terms of dwelling units may be divided into three general forms of action:

Prevention of accelerated rates of deterioration of dwellings and their environment, thereby forestalling the formation of new blighted and slum areas;

Rehabilitation of existing substandard housing, if salvage is economically feasible, and the demolition—which is part of rehabilitation in its broader sense—of substandard dwellings that are beyond repair;

Production of enough new housing to provide for the population increase, for families

now overcrowded, for replacement of demolished and decayed structures, and for the normal vacancy cushion.

In short, prevention, rehabilitation, and production are all necessary to improve housing conditions. In these areas, special responsibilities have been assumed by private enterprise and Federal, State, and local governments. In prevention and rehabilitation especially there is an underlying essential—an informed citizenry.

Private Enterprise

The role of private enterprise in attacking the housing problem has been well defined over the years. Industry produces the materials used in the construction of all housing, including improvements and ancillary utilities and facilities. The private builder and contractor erect almost all new housing, including that small segment which is built for public ownership. Private enterprise sells most new and existing housing. Private capital, with some assistance from government, provides the financing essential for almost all new construction and for most substantial improvements to existing housing. That private capital and industry can and do handle such a large part of the task is characteristic of this Nation.

Federal and State Government

Federal and State governments provide assistance and services that individuals and organizations cannot provide for themselves. Federal legislation provides assistance with the insurance of mortgages, with the insurance of deposits in home loan banks, with mortgage money market financing, slum clearance and urban redevelopment, low-rent public housing, research, loans and grants for farm housing, rent control, and with the collection of national statistics on housing, labor, and building materials. Furthermore, the Congress of the United States has established a national housing policy stating that "the health . . . of the people, requires . . . as soon as feasible a decent home and a suitable living environment for every American family . . ." (5).

State governments provide assistance primarily with public housing, slum clearance and urban redevelopment, regional planning, and basic legislation and police powers authorizing certain regulations.

Local Government

It is of prime importance that the programs of all agencies of local government having anything to contribute toward better housing—and it is a surprising number—be coordinated and be undertaken in a spirit of cooperative action. Cooperation of the local health department is especially important because the basic police power of the State to regulate must be reasonably related to welfare, morals, safety, or *health* if the regulation is to be held valid. Consideration of the housing problems of the other

agencies of local government will materially assist the health official to carry out the health department program with the maximum effectiveness; the opposite, of course, is equally true.

Building Department

The primary function of the building department is to administer the building code which regulates the construction of new dwellings and major structural changes or additions to existing dwellings.¹ The building department issues licenses in the form of building permits

¹ A full and detailed discussion of building regulations has been presented by McGoldrick and associates (6).

authorizing new construction. It also enforces compliance with the electrical code, with structural requirements, and usually with the plumbing code for new dwellings. The provisions of the building code regulate such items as light, heat, ventilation, and plumbing facilities for new structures. These are obviously related to health department interest. Significantly, moreover, the building code fixes the dwelling problem which the health department will inherit in a decade or two, or three, as deterioration takes place and health problems arise.

Planning Department

The planning department is concerned with the physical facilities of the community and the location of these facilities for the benefit of the people. Housing in its broadest sense is an important part of these physical facilities. The quality of the dwelling and its environment as a healthier place to live is affected by the size and location of streets, by the location of parks, playgrounds and schools, by the location of water and sewer lines and other utilities, and by the type and location of community facilities. The control that planning and zoning officials can exert over the development of new subdivisions, coupled with health department participation, can curtail, if not eliminate, urban fringe sanitary problems.

The Zoning Board

The zoning board is usually administratively related to the planning department. It administers the zoning code which fundamentally regulates the height of buildings, the density of land coverage, and the use of land in the interest of the general welfare and health of the community and for the protection of land values. The zoning board has the authority to prevent intermixture of land use, to prevent subdivision of large dwellings into multiple units where kitchen and bath facilities are frequently shared, to regulate lot size and percent of land coverage, and to regulate the height and separation of buildings and dwellings. Obviously, the health official has direct interests in these activities.

The Fire Department

In the context of this discussion the inspec-

tion service of the fire department is concerned with the design, construction, and maintenance of multifamily dwellings, rooming houses, hotels, and public buildings in the interest of protecting the occupants and the community against injury or death by conflagration or explosion. The dimly lighted public hall, the deteriorated stairway, the anxiety of occupants with a single means of egress, and the accumulation of rubbish or trash are as much the concern of the health official as of the fire official. Thus, health and fire departments have a number of related interests with respect to the housing problem.

Welfare Department

The welfare department provides financial assistance for families with insufficient means. At least one-fifth to one-third of these family funds are used for rental payments for housing. Although welfare departments consistently try to help families obtain the best housing possible, it is well known that welfare funds, for the most part, are only sufficient to obtain substandard housing. This situation requires administrative cooperation between health and welfare officials in the local government and subsequent citizen support.

The rental payments of welfare departments are a tremendous resource that may be used in attacking the poverty aspects of the housing problem. According to the *U. S. Municipal News* (7), 4 percent of the population of 25 leading cities in 1948 were on relief and received an average monthly payment of \$34 a person. If we apply these average figures to the population in urban areas and consider that one-fourth to one-third of these funds are used for rental payments, it may be conservatively estimated that some \$25,000,000 to \$30,000,000 per month of welfare funds are being spent for rental payments. Since much of this sum pays the rent for substandard housing, this in effect subsidizes such housing.

Although the rents for substandard housing are low in terms of dollars, they frequently are high in terms of the space and facilities provided. These comparatively high rates of rent on slum properties are too well known to merit elaboration. However, experience in several communities has demonstrated that improvements can be made in many dwellings without

substantially increasing the rent and still allow a reasonable return on the investment to the owner. Of course, this is not the case for all improvements.

Although welfare departments make an effort to establish certain standards for housing to be occupied by relief clients, minimum health standards of housing, in the last analysis, must be based on the health aspects of the police power of the States. The primary responsibility for the development, application, and enforcement of the health aspects of the police power is generally vested in health officers. If then the health official establishes minimum housing standards, and the welfare department adopts the policy of making rental payments only for those dwellings which meet these minimum standards, it will be possible to bring to bear the leverage of these tremendous payments to obtain improved housing conditions.

Housing Authority

The local housing authority is established as a corporate body of the community through State enabling legislation. This legislation primarily authorizes the housing authority to issue municipal-type bonds to provide the capital for building public housing units and to accept Federal payments to equalize the deficit between costs and income.

These dwellings are constructed for low-income families who cannot obtain or provide decent, safe, and sanitary housing for themselves at an economic rent in the community. A number of health problems arise in the location, construction, and management of public housing projects. Many important public health problems related to public housing developments, such as site selection, re-use of cleared land, and occupancy and management, can be averted by sanitary engineering advice (8). Since the housing authority and health officials are concerned to a considerable degree with similar areas in the community, they have a number of mutual problems (9).

Slum Clearance and Urban Redevelopment Agency

The slum clearance and urban redevelopment program was initiated as a result of the Housing Act of 1949, which authorized funds for loans and grants to local agencies primarily for

the purpose of assembling and clearing slum land for re-use. Ordinarily the cleared land will be re-used for housing purposes. However, its use must be in conformance with the requirements established by the master plan of the community. Many health problems arise in determining the best re-use of land in slum areas. Furthermore, the law requires that persons displaced from the cleared areas must be rehoused in decent, safe, and sanitary dwellings under reasonably equivalent conditions. The health official can make a real contribution to the determination of such dwellings and choice of areas for redevelopment (10).

Health Department

The principal housing responsibility of the health department is the administration of the housing code regulating the facilities, maintenance, and occupancy of existing dwellings. Although the minimum standards contained in the code are applicable to all dwellings, obviously they are primarily applicable to substandard housing.

The first step in this task is to diagnose the problem. To do this the health department must obtain the facts. The Committee on the Hygiene of Housing of the American Public Health Association has devised an objective method for measuring the quality of housing and its environment in a community (11). Many local health departments across the Nation have already used this method to study the housing problem.

Through an agreement between the American Public Health Association and the Public Health Service, training in the use of this method is available at the Public Health Service housing training stations at Atlanta, Ga., and Syracuse, N. Y. Follow-up assistance is also provided. No charge is made for the course, but the trainee must provide for his own subsistence and quarters. Approximately a quarter of a million dwelling unit schedules and related environmental data have been completed by using this method.

Communities report that the information obtained through this appraisal method is useful to so many agencies of local government that it is an important administrative device for obtaining interagency cooperation. However, ir-

respective of the appraisal method chosen to measure the housing facts in a community, it is imperative, from an administrative standpoint alone, to use a method that provides the essential information for all of the agencies concerned. The method must be objective, reducible to a numerical basis, and produce results subject to disciplined analysis. Of course, it should be possible to reproduce and to validate the results.

Whether this or some other survey method is used, the health department must obtain detailed facts concerning the housing problem in the community. As is customary with health problems, the facts of the situation must be presented to the public so that the community may have the necessary information to use as the basis for the choice of remedial action.

This leads to the second step, which is to tell the story of housing to the public. It has been clearly demonstrated in several communities that informing the public regarding existing housing conditions is an essential part of a housing law enforcement program (12). It is not enough to make broad general statements and propose general programs; specific information must be obtained so that detailed facts may be stated and action policies formulated.

Once the specific information has been obtained and presented to the community, the third step, the formulation of minimum health standards for housing and adoption of laws for their enforcement, may be intelligently accomplished. The persons to be affected by these standards and laws—the housing code—should be given an opportunity to be heard, to present contrary evidence or opinion, and significantly to help define for the administrator the level of community acceptance of the proposed regulations.

However, laws are not self-enforcing. Once they are established, the actual accomplishments of enforcement—the fourth step—stands or falls on the judgment, the efficiency, and the impartiality with which the laws are administered. Since some of the principles of housing law enforcement have been discussed before (13) suffice it to say that effective action cannot be expected without adherence to good administrative-legal practices.

The housing law enforcement program is not

the only responsibility of the health department in the solution of the housing problem. The health official has an important job to do in assisting all the other departments of local government to accomplish their housing tasks. Examples of areas of common interest with other local governmental agencies were previously discussed and need for cooperative action was emphasized. As health officials become familiar with the housing programs of other agencies in the community, they will be able to contribute substantially to the improvement of housing in terms of both immediate action and long-range programs.

Clearly, the maximum community benefit from housing law enforcement activities of the health department cannot be obtained if the program is conducted in isolation. It is necessary for the health department, in conjunction with all other official agencies of government and with representative community organizations concerned with the housing problem, to decide on the extent and area of enforcement. It is particularly important, of course, that the housing law enforcement program be coordinated with the programs of the slum clearance and urban redevelopment agency and the housing authority, rental payments of the welfare department, and the master plan of the community.

Urban Nonfarm and Rural Housing

Housing is by no means entirely an urban problem. Numerous studies have been made of substandard housing in the small cities and rural areas as well as in the metropolitan communities (14, 15). Unfortunately, most of the

local agencies referred to do not exist in small communities or rural areas. If they do, they seldom are staffed to carry out the housing functions referred to previously. This increases the importance of housing action by local health departments, where they exist, or by State health departments having jurisdiction in small communities and rural areas.

Although only a very few rural public housing authorities are in existence, there is a trend toward development of public housing programs in small communities. The need for participation of health officials in the health problems of these developments is comparatively greater than in the large cities.

The Housing Act of 1949 recognized the need for assistance in rural housing problems and provided loans and grants for housing improvements to owners of farm dwellings unable to obtain financial assistance elsewhere. This program is administered by the Farmers Home Administration through its state directors and the county agents of the Department of Agriculture. The Farmers Home Administration has adopted rules and recommendations establishing minimum standards for construction and repair of dwellings (16). These standards cover items relating to light, ventilation, room size, site location, water supply, plumbing, sewage disposal, heat, and other items of special interest to health officials, and require compliance with local regulations.

Certainly substantial improvements to farm dwellings, including the water supply and sewage disposal facilities, can be made through cooperative effort between local representatives of the F.H.A. and health officials.

Discussion

The Nation's housing problem has developed over a period of a century or more. The prevention of decay of dwellings and their environment, the rehabilitation of existing substandard housing, the demolition and replacement of dwellings beyond repair, and the production of enough new housing present enormous difficulties. Dollar estimates of the cost of such a program are staggering. A successful beginning has been made, and there can be extensive progress with present-day knowledge. We should

expect substantial results in one generation.

No single agency of government or industry working alone can solve the total housing problem; the solution depends on the combined efforts of Federal, State, and local government, and private enterprise with the active support of informed citizens all working as a team. The health department is an important member of this team.

Evaluating Health Education

By ANDIE L. KNUTSON, Ph. D.

Health people frequently ask: How can we tell if we are accomplishing anything? What methods should be used to evaluate our work? What are the criteria for effectiveness in health education?

This paper is a general approach to, or a philosophy of, evaluation. It outlines some basic concepts to consider when planning and conducting health education evaluation. The concepts, although presented independently, are closely interrelated and supplement each other.

Three things of utmost importance in evaluating health education are (a) the correct selection or development of methods, (b) the proper use of the methods selected, and (c) the sound interpretation of the data obtained. Given below are a few basic guidelines which should be considered in selecting, applying, and interpreting the techniques of measurement used in evaluating health education.

Exploratory Fact-Finding

Planning evaluation studies of health education requires adequate exploratory fact-finding. Such explorations should be considered as part of planning a health education program. They should assure that the program is directed toward satisfying expressed needs or interests of the people for whom it is designed and that the methods used tie in with existing behavior patterns. Careful exploration is particularly necessary when the program aims to change behavior. If such problems are not considered

as part of planning a health education program, it may be based on false or inaccurate assumptions regarding behavior and have little possibility of success. Later efforts at evaluation would have limited or no value.

For example, before attempting to measure the effectiveness of a program to inform people about the nutritional value of proteins, carbohydrates, vitamins, minerals, and fats, one must know what meanings these terms convey. How can the concepts described by these terms be most easily incorporated into the usual pattern of living? Do people shop for proteins and carbohydrates or do they buy meat, vegetables, and baked goods? How can they improve their food habits with a minimum of change in their current patterns of buying food and planning meals?

A program designed to increase the use of milk may miss its goal if the people for whom it is planned do not consider milk an essential food. Or an information program on the early symptoms of cancer may not lead to action unless these symptoms are described in terms people understand and can recognize.

Specific Goals

The broad purposes of an educational program must be broken down into specific, concrete, definable goals before evaluation can be undertaken. When the objectives are fully and concretely defined, one can determine in advance what kind of data will yield the best evidence of their achievement. A study design can then be developed to collect the necessary data.

On the other hand, if an over-all evaluation is attempted without breaking the broad purposes of the program into specific goals, the results are likely to be inadequate, yielding personal impressions rather than objective meas-

Dr. Knutson, a social psychologist, formerly was associate director of the Office of Public Opinion Research of Princeton University. He is now chief of the experimental and evaluation services branch of the Division of Public Health Education, Public Health Service.

urements. (See references 1, 2, and 3 for experimental evidence of the errors which result when general ratings are used in attempting over-all evaluation.) Such impressions will vary according to the experiences and interests of the persons doing the evaluating. As shown by studies in social psychology (4), each evaluator will tend to see in the program the things which are meaningful in terms of his own experiences. He will judge it against his own unique and undefined scale of values. One evaluator may view a part of the program in which he is interested and judge it to be good; another may rate this same part as poor; while a third may not even consider it to be significant and will base his judgment on some other aspect of the program. In the end, the evaluation is essentially a variety of unrelated personal opinions.

General vs. Specific Evaluation

The interrelationship between the findings on the achievement of specific goals must also be considered. The whole is greater than and sometimes different from its parts. While a general evaluation may be referred to as such, in practice it means that an empirical judgment has been made, based on various specific evaluations.

In making a general health examination, the doctor measures specific things, such as height, weight, blood pressure, pulse, and vision. His general evaluation is limited by the degree to which he can break it down into measurable specifics and by his understanding of the interrelationship of these specifics. At the same time, the examination is limited by his own experience, through which he has learned to see certain things to the exclusion of others, and by his own concept of general health as it relates to a patient. Accuracy in interpretation is limited to a person's ability to perceive and to understand. Thus, a general practitioner might have difficulty in diagnosing an unusual illness because he does not know the specific disease, because he has had no experience in detecting it, or because the disease is completely unknown.

As the doctor acquires broader experience and his tools become more numerous and refined, he can evaluate specific items in the general examination with a higher degree of precision and

reliability. Accordingly, the results of his general examination gradually approach a total evaluation of his patient's health.

The measure of success of an activity is how well it achieves its intended purpose. This principle applies no matter what the purpose, whether it is to raise curiosity, to inform, or to produce action.

Health materials or programs may also provide information or influence behavior in some way other than the one intended. A person reading a health pamphlet, seeing an exhibit, or having some other educational experience may find in it something that directly ties in with his experiences and interests and thereby helps him to achieve his own goals. His knowledge, understanding, and behavior may all be influenced. He would probably consider the materials or program very successful.

From the point of view of the educator, however, such materials or programs should not be considered successful unless the intended objectives are also achieved. It matters not if the action caused is even more desirable than the action hoped for. To interpret as indications of success evidence of behavior changes other than those intended is to set up *post hoc* objectives.

Success, from the viewpoint of those who plan materials or programs, need not conflict with success from the standpoint of the persons for whom they are planned. Studies of human behavior suggest that educators will be most effective in achieving their purposes when such purposes are defined in terms of the wants and goals of members of the intended audience and are tied in with their way of life.

Criterion of Effectiveness

Concrete evidence that an objective has been achieved is the only realistic criterion for measuring effectiveness. Such evidence should be distinguished from criteria which measure some of the conditions necessary to achieve the objective.

The number of items of material distributed, the number of persons attending a movie or exhibit, the amount of attention attracted by exhibits or other materials, the level of readability, and similar items represent conditions

necessary for effectiveness, although they are sometimes cited as measures of effectiveness. Certainly a movie, an exhibit, or a lecture must be seen, read, or heard to be effective, but that may not be sufficient. The observer may still be left uninformed, misinformed, or with negative attitudes, and may take no action.

The difference between conditions necessary for effectiveness and evidence of effectiveness itself is generally accepted in psychological research but is not yet widely recognized in health education. Attention has been called to it by Derryberry (5) as follows:

... in the past, counts of the numbers of spectators and average observation time have been cited as positive evidence of an exhibit's effectiveness. However, such records do not constitute positive evidence of the effectiveness of exhibits, because the records fail to indicate what, if anything, the spectator learns. Certainly there is no assurance that he is learning the message intended. So far as can be detected from observations, the visitor may be drawing wrong conclusions from the material in the display. Consequently, it is apparent that such records are valuable only in a negative sense—negative in that an exhibit cannot be effective as an educational medium if it fails to attract attention of visitors or fails to sustain their interest long enough for them to complete inspection of it.

The failure of a program to satisfy the conditions necessary for effectiveness leads to a screening out of some members of the potential audience. For example, all members of the potential or intended audience who did not receive a pamphlet, attend a movie, or see an exhibit (were not exposed to the educational effort) are eliminated because one of the conditions for effectiveness (exposure) was not met. Similarly, lack of interest and understanding will screen out other members of the intended audience. The fact that some individuals were not screened out by these limiting conditions and did participate in the program is not adequate evidence, however, that the program was successful for them (6).

Selection of Methods

The method used to evaluate a program should be especially selected or constructed in terms of the particular goals to be reached. Accordingly, evaluation plans should be devel-

oped along with program plans. Developing evaluation plans at this time will help to assure that the goals are specific and that steps are taken to obtain an adequate base line from which to measure change. The evaluation approach and findings can thus be tied in more closely to program needs, goals, and methods so that the findings will be of maximum use to those carrying on the educational program.

Two serious hazards are involved in the alternative practice of developing a list of evaluation techniques and then selecting from this list certain procedures to measure a program's achievement. First, the technique most effective for evaluating one program may prove worthless in another because of differences in goals or in methods of approach. No one technique of evaluation is adequate for all situations. Secondly, there is always the danger that some technique will look particularly interesting and changes will be made in the program to facilitate its use. This aspect of technique influencing the definition of problems and goals is one of the greatest dangers in social research (7).

The Base Line

The measures used to evaluate health education seldom start from absolute zero. Individuals have invariably acquired some health knowledge, attitudes, and practices before a program starts. A base line of zero cannot usually be assumed.

The evaluator who studies the effectiveness of a nutrition education program, for example, must recognize that individuals already have considerable information about food, although some of it may be incorrect. They have also developed definite food attitudes and practices before participating in the program. Some base line of their present knowledge, attitudes, and behavior, therefore, must be obtained prior to estimating changes.

Such a base line should be viewed as a relative rather than an absolute starting point. It usually describes the average situation at the beginning of the program and indicates the degree to which individuals vary about this average. Gains should be interpreted as progress from this average starting point rather than as progress from zero.

A corollary to the preceding concept is that the measurements employed in evaluating health education seldom, if ever, have equal psychological units. The units within a scale of measurement usually vary somewhat, making interpretation of data difficult.

For example, it is erroneous to infer that a person who scores zero on a test has no information, positive attitudes, or practices, or that a person who gets a perfect score is completely informed and wholly positive in attitude and action. Likewise, a person who receives a score of 80 cannot be considered to be twice as educated as one who obtains a score of 40. Even individuals who obtain identical scores cannot be assumed to have identical knowledge or understanding.

The Indirect Nature of Measurements

Evaluative measurements are nearly always indirect measures of the effects of the program on behavior. The findings of evaluation must be interpreted with full recognition of the specific indices used for measurement.

The personal and social variables being measured in a health education program are more complex than the variables in physical objects. For example, units of measurement for weighing yield only indirect evidence of the weight of an object. The standardized unit for such weighing, however, has been in use for so long that weight given in these units is accepted as direct evidence of the object's weight.

No comprehensive standards have been developed to measure all the personal and social variables in human behavior. New scales of measurement must be devised and validated almost every time one attempts to determine the amount and accuracy of a change in a person's information, the direction, extent, and intensity of a shift in attitudes, or the nature and direction of an adjustment in behavior. Each scale of measurement so developed provides only sample evidence on the behavior being measured.

As Thorndike (8) has pointed out, intelligence cannot be measured directly, nor is it known for certain what intelligence represents. Intelligence tests measure the effects or products of intelligence. They have proved useful for interpreting behavior and for making pre-

dictions about future behavior. In interpreting the findings from such tests, however, it is essential to bear in mind that intelligence is inferred from indirect evidence.

Likewise, in attempting to measure attitudes or changes in behavior, the data are limited to the things that can be observed in verbal or physical behavior. Great caution should be observed in imputing meanings or motivations to the data observed.

Planning for Future Needs

Each practical evaluation should be planned to satisfy long-range needs of health education while meeting the immediate project requirements. Each study will then contribute toward the testing of some long-range hypothesis or principle without much additional cost or effort. The findings of different studies will supplement each other in a more meaningful way while unrecognized duplication of effort is minimized. Otherwise, evaluations may yield isolated bits of information that contribute little or nothing toward improving educational methods. The findings should help to answer the challenges so often made: If this won't work, what will? How can this evaluation help us to do it better the next time? How can we relate these results to the findings of other studies?

Thus, evaluators are faced with two questions. The first is: How can evaluations of a specific program be made more meaningful and useful to those responsible for achieving immediate program goals? The answer to this question calls for better experimental design for each study.

The second question is: How can an evaluation of a specific program be made to furnish data for long-range needs? The answer to this more fundamental question requires planning at a broader level. As Marquis (9) has pointed out:

Research planning can be carried out at different levels. I would like to distinguish three levels which I will call experimental design, program design, and policy design. Experimental design is the planning of a single specific project. Program design is the planning of an integrated set of projects focused on a central problem. Policy design is a new word for over-all planning of the

distribution of effort among programs, areas, or fields.

The field of evaluation in health education is particularly weak in the program and policy design levels of research planning. If studies of evaluation are planned in terms of these broader frameworks, the evidences that accumulate will gradually satisfy the long-term as well as the short-term needs of health education and provide a sound basis for program planning. Is it reasonable to anticipate that from such studies might eventually develop a science of health education?

The problems involved in measuring personal and social variables might lead some people to say that the effectiveness of health education in changing behavior cannot be measured. This defeatist viewpoint has no basis in fact. To cite Thorndike, "Whatever exists at all exists in some amount" (10) and can, therefore, be measured. As the programs of health education are more clearly conceptualized, effective means can and will be developed to evaluate them.

Summary

Basic concepts that should be considered in evaluating any health education program are:

1. Planning evaluation studies of health education requires adequate exploratory fact-finding.

2. The broad purposes of an educational program must be broken down into specific, concrete, definable goals before evaluation can be undertaken.

3. The interrelationship between the findings on the achievement of specific goals must also be considered.

4. The measure of success of an activity is how well it achieves its intended purpose.

5. Concrete evidence that an objective has been achieved is the only realistic criterion for measuring effectiveness.

6. The method used to evaluate a program should be especially selected or constructed for that program in terms of the goals of the program.

7. The measures used to evaluate health education seldom start from absolute zero.

8. Evaluative measurements are nearly always indirect measures of the effects of the program on behavior.

9. Each practical evaluation should be planned to satisfy long-range needs of health education while meeting the immediate project requirements. 1

ACKNOWLEDGMENT

The author wishes to acknowledge the assistance of Dr. Mayhew Derryberry, chief of the Division of Public Health Education, and of members of the division who contributed to the development of this paper.

Studies in Penicillin Treatment of Syphilis

By R. C. ARNOLD, M. D., J. C. CUTLER, M. D.,

R. D. WRIGHT, M. D., and S. LEVITAN, M. D.

More than 7 years have elapsed since the efficacy of penicillin in the treatment of early syphilis was first reported (1). In this relatively short period, penicillin has been adopted throughout the United States, and much of the world, for the treatment of all stages of syphilis. Concepts of epidemiology, immunology, serology, and treatment have been radically altered. The hazards of the antisypilitic therapies of the past have been eliminated; the treatment period has been shortened from years to days; and a modern type of "therapia sterilisans magna" has been realized. These factors have brought about many necessary adjustments as well as advantageous developments in the administrative, clinical, and educational phases of venereal disease control.

Of the several specifications for an ideal therapy, cure of all patients is of primary importance. Unfortunately, this goal has not yet

been attained. All treatment schedules, both old and new, which have been used on 100 or more patients with early syphilis have had true failures or relapses in addition to established reinfections. Nevertheless, penicillin excellently fulfills the aims of a practical therapy—to cure with safety, simplicity, and economy a high percentage of those treated in the early stages.

During these formative 7 years there have been many improvements in the antibiotic agent and in the complementary vehicle for administration. The subsequent adoption in rapid succession of various therapeutic schedules and drug refinements has made comparative evaluation difficult; but it has provided comprehensive experimental data upon which the optimal time-dose relationship can be established. From the variety of studies thus engendered it has become clear that penicillin therapy can safely and quickly eliminate the early infectiousness, as well as the potential late complications of the disease, in all who respond to standard treatment. Only a small minority need individualized re-treatment at a later date.

Dr. Arnold is chief of the technical services branch, National Heart Institute, of the National Institutes of Health, Public Health Service. Dr. Cutler is chief of the technical aids and services branch, Division of Venereal Disease, Public Health Service. Dr. Wright is with the University of Virginia at Charlottesville. Dr. Levitan is chief of the yaws and syphilis control program of the United Nations International Children's Emergency Fund, World Health Organization, Port-au-Prince, Haiti.

The authors of this paper have all served at the venereal disease research laboratory of the Public Health Service, where these studies were conducted. The laboratory was transferred from Staten Island, N. Y., to Atlanta, Ga., in March 1950.

This paper reviews the results of the studies in developing penicillin therapies undertaken from 1943 to 1950 in the venereal disease research laboratory. Throughout this period our patients were predominantly young white males; only about 3 percent of the total study group were females. All clinical diagnoses were confirmed by laboratory findings and, so far as is known, no previous therapy for early syphilis had been received by any of the patients included in the study groups. The ratio of primary to secondary syphilis is indicated in the accompanying tables for the various treatment schedules. All patients were hospitalized for pretreatment diagnostic study, for therapy, and, whenever possible, for special post-treat-

ment examination when reinfection or treatment failure was suspected or when serologic reactivity was unusual.

Early Penicillin Schedules

After animal experimentation indicated that penicillin possessed spirocheticidal activity, a human pilot study was initiated in June 1943 (1). In this study four men with darkfield-positive primary syphilis received 1,200,000 units of amorphous penicillin in aqueous solution, in 48 doses of 25,000 units each, administered intramuscularly at 4-hour intervals for 8 days. When the four men were re-examined 6 years later, detailed clinical examinations and serologic studies were negative (2). Three of the men had maintained seronegativity since the second or third post-treatment month. The fourth had been clinically negative 10 days after therapy and serologically negative in a battery of diagnostic tests at 71 days. The negative findings persisted up to 286 post-treatment days, when his serology showed strongly positive; clinical examination revealed a new darkfield-positive chancre on the lip, and an acute gonococcal urethritis. Following a second course of penicillin, the clinical manifestations disappeared and the blood tests reverted to negativity.

These four patients, as well as many others, have been successfully treated with aqueous penicillin, as indicated by 36 or more months of observation. With each of the several time-dosage combinations which have been tried, a good proportion of observed patients quickly reached and maintained both clinical and serologic negativity. Although failure rates in certain schedules were too high for practical purposes, the over-all picture confirms the efficacy and adaptability of penicillin in the treatment of early syphilis.

Aqueous Penicillin Schedules

The second treatment schedule used at this laboratory consisted of 20,000 units of aqueous amorphous penicillin administered intramuscularly every 3 hours for a total of 60 doses, or 1,200,000 units (table 1, schedule A). An early review of this schedule indicated that it might

be unsatisfactory (3); and by 21 post-treatment months a cumulative re-treatment rate of 32.8 percent among the secondary syphilis patients confirmed the earlier decision to seek a more effective regimen.

The total dosage was doubled for the next schedule: 40,000 units of penicillin was administered intramuscularly every 3 hours for 60 doses, or 2,400,000 units. The cumulative re-treatment rate for secondary syphilis patients was 20.1 percent by 21 months (table 1, schedule B). It should be pointed out that the numbers of patients so far treated and observed were small in each diagnostic category, which made comparison of rates somewhat difficult between schedules. Nevertheless, in this latter schedule, the re-treatment rates as well as the seronegativity rates among observed patients showed, in general, considerable improvement over the previous schedule. In addition, it can be stated that among our predominantly male patients there were proportionately fewer clinical and serologic failures observed with 2,400,000 units than with 1,200,000 units. Space limitations, however, do not permit showing the reasons for re-treatment on the accompanying tables. Sternberg and Leifer (4) reported good results with 2,400,000 units of amorphous penicillin administered to a large group of young males on the same time-dosage regimen.

Elsewhere, evaluation studies by the Division of Venereal Disease of the Public Health Service, based exclusively on patients treated for secondary syphilis, showed similar cumulative re-treatment rates by 21 months: 27.6 percent with 1,200,000 units, and 22.4 percent with 2,400,000 units of aqueous amorphous penicillin (5). However, these studies included much larger groups of patients, both male and female, white and nonwhite, drawn from several clinics. On such a basis, it became clear that the larger dosage of amorphous penicillin offered no essential advantages over the smaller dosage.

In the present report, we have used the method of statistical evaluation developed and employed by the Division of Venereal Disease, Public Health Service (6). However, it should be remembered that our patients were predominantly young white males—a factor which might be expected to produce differences from

results shown in other studies in evaluation of a particular therapy. One report on the probable influence of the factors of race, sex, and stage of syphilis on results of therapy (7) indicates that white males will usually have a lower re-treatment rate than Negro males in the two primary stages of syphilis; that in white male patients the cumulative re-treatment rate for

secondary syphilis will be higher than the rates observed in seronegative and seropositive primary syphilis; but that no significant differences were observed between the four groups (white and Negro, male and female) in patients treated for secondary syphilis.

Experiments with aqueous amorphous penicillin solutions indicated that when the interval

between injections was reduced from 3 hours to 2 hours more constant and higher penicillin blood levels could be maintained in a larger proportion of patients (8). Consequently, in the next investigative schedule the interval between injections was reduced: 20,000 units (amorphous) was given every 2 hours for 85 injections, to a total of 1,700,000 units. By 21 post-

treatment months the cumulative re-treatment rate for secondary syphilis under this schedule was 26.6 percent among observed patients (table 1, schedule C).

Then a 3,400,000-unit schedule, consisting of 85 intramuscular injections of 40,000 units of aqueous amorphous penicillin every 2 hours, was tried (9). The cumulative re-treatment rate

Table 3. Penicillin levels of blood after single injection of procaine penicillin G in oil with 2 percent (w/v) aluminum monostearate

Dose of penicillin (units)	Total patients	Percent of total patients showing detectable levels at 72 hours	Average penicillin blood levels (units per cc. of serum) among patients showing a detectable concentration			
			24 hours	48 hours	72 hours	96 hours
300,000	374	97.0	0.094	0.060	0.042	0.034
600,000	98	96.0	.205	.122	.111	.077
900,000	21	100.0	.245	.185	.153	.124

schedule A. In spite of the small numbers in each diagnostic category, however, this schedule showed good results, in our opinion, and offered an adaptable regimen for out-patient therapy in early syphilis. No clinical relapses were noted among primary and secondary syphilis patients who remained under observation; and only 2 patients (with secondary syphilis) were re-treated on the basis of serology. By the fifteenth post-treatment month, the cumulative re-treatment rate in the secondary syphilis group was 14.5 percent (probable reinfection rate, 7.1; serologic failure rate, 7.4).

Single-dosage Schedules

In the next schedule studied, a single dosage of 900,000 units of procaine penicillin G in oil with 2 percent aluminum monostearate was used. Twenty patients were treated for primary or secondary syphilis. Sixteen of the patients were observed at the third post-treatment month, and 10 patients were seen at 15 months. One of the observed group was reinfected at 154 days and was re-treated with the same dosage. After re-treatment, clinical manifestations disappeared and blood tests reverted to negativity for the second time, and remained so. Another patient had positive spinal fluid findings when observed at 448 days; and was re-treated with 600,000 units daily for 6 days. The 900,000-unit schedule was discontinued at our laboratory when it was noted that other investigators were using a slightly larger single dosage—1,200,000 units (20). However, our investigation of single-dosage therapy was continued with smaller amounts of penicillin.

Alexander and Schoch (21, 22) and Plotke and associates (23) had shown the dramatic ef-

fect of abortive or prophylactic therapy in contacts exposed to active syphilitic infections. We believed that experimentation with a penicillin dosage lower than theirs would yield significant information on the response in syphilis to the therapy generally used for gonorrheal infections. More than 100 patients with early infectious syphilis were treated with a single intramuscular injection of 300,000 units of procaine penicillin in oil with 2 percent aluminum monostearate. Special studies were made of penicillin serum concentrations, clinical and serologic reactions to therapy, and response to re-treatment (8, 19, 24). Full reports on certain aspects of these studies will be published at a later date. No treatment failures were observed in the seronegative primary syphilis group, but the otherwise high cumulative re-treatment rates of the 300,000-unit schedule led to its discontinuance. By 12 months the re-treatment rate was 28.4 for secondary syphilis, and 12.7 for seropositive primary syphilis; and additional failures were seen after this period (table 4, schedule B). Nearly all the re-treated cases were true treatment failures, including one with positive spinal fluid findings. However, three significant facts were revealed: (a) seronegative primary syphilis shows adequate response to a single injection of 300,000 units of procaine penicillin G with aluminum monostearate; (b) a large percentage of patients with seropositive primary syphilis can be expected to respond satisfactorily to as little as 300,000 units of this penicillin product; and (c) a single-injection or one-session schedule of intramuscular penicillin therapy can be developed for the cure of early syphilis, dependent upon the determination of the proper dosage of a slowly absorbed compound of the drug.

Serum concentration studies indicated that

600,000 units of procaine penicillin in oil with 2 percent aluminum monostearate might be expected to produce a more effective therapy than 300,000 units (table 3). To determine the minimal effective dosage for a majority of patients—a matter of extreme importance in areas where penicillin is scarce or expensive—an experimental single-dosage schedule of 600,000 units was set up. Results are inconclusive at this writing because of too few patients and insufficient observation. Eighteen patients with primary or secondary syphilis were treated; 14 of these were seen at the third month and 10 remained under observation at the seventh month. So far no failures or reinfections have been observed among the small group.

Central Nervous System Syphilis

It has been difficult to evaluate the therapeutic effect of the different penicillin schedules on syphilis of the central nervous system. One of the reasons for the difficulty has been that only a limited number of such patients were admitted for therapy. The results of studies of penicillin concentrations in the blood and spinal fluid have been influential in formulating our current therapy for this complication. In one study (25), penicillin levels in the cerebrospinal fluid were determined on 198 specimens taken from 114 patients at various time intervals during and after a regimen of six daily injections of procaine microcrystal penicillin in oil with 2

Table 4. Treatment of early syphilis with procaine penicillin G in oil with 2 percent aluminum monostearate

percent aluminum monostearate, in doses of 600,000 units. Detectable levels of penicillin were obtained from 2 to 290 hours after beginning the injections, with 82 percent of the specimens showing a level at 31 hours and 91 percent at 122 hours. Between 31 hours and 194 hours, penicillin was detectable in 75 percent of 110 specimens. On the basis of this and other supporting data (8), we adopted the schedule of 600,000 units for six daily consecutive doses for the treatment of central nervous system syphilis.

Favorable response has been reported by Dattner, Curtis, Stokes, and their co-workers (26-28) and by other authors in nearly all complications of the nervous system when penicillin without adjuvant therapy is used. Research groups in the United States are almost unanimously agreed that arsenic and bismuth are without value as adjuvants to penicillin in the treatment of neurosyphilis. Most investigators also believe that fever therapy should be avoided until penicillin has been proved deficient in a particular case, inasmuch as repeated courses of penicillin in higher amounts have been shown to be effective in a large proportion of both symptomatic and asymptomatic neurosyphilis patients who required additional treatment. An occasional late serious manifestation of neurosyphilis may require the added support of fever therapy, but the consensus of research observations at this time appears to favor penicillin as the initial course of therapy for most types of neurosyphilis. Long-term evaluative studies in this field should continue to provide definitive answers for all the ramifications of late syphilis.

Spinal Fluid Findings in Early Syphilis

Abnormal spinal fluid findings were found upon admission in about 7 percent of a large series of patients. These were usually slight deviations from normal in one or more of the test methods employed (Kolmer complement-fixation test, Eagle flocculation test, cell count, total protein determination, and colloidal gold reaction). None of the patients showed clinical evidence of central nervous system involvement. After penicillin therapy the spinal fluid became negative and remained negative in all those patients who continued under observation.

Among those patients whose pre-treatment spinal fluid findings were essentially negative, only two were observed later with neurorelapse. Both had secondary syphilis at the time of their original treatment with amorphous penicillin; one with 1,200,000 units and one with 2,400,000 units. In both cases we had observed indications of blood serologic relapse just prior to the clinical examinations which revealed the post-treatment positive spinal fluid findings. The first patient returned in the sixth post-treatment month with an acute meningeal type of relapse, and his spinal fluid examination showed the reactions to be: Kolmer 4444-, Eagle positive, colloidal gold 1112220000, cells RBC, globulin normal. After an intensified course of penicillin therapy, he gradually attained negativity in every respect. The second patient returned in the fourth post-treatment month and was re-treated with an intensified schedule for serorelapse and asymptomatic neurorelapse (Kolmer 442± - -, Eagle positive, colloidal gold 4311100000, other tests normal). He quickly attained and maintained negativity in all tests, in spite of a reinfection for which he was re-treated within the first year.

In the single-dosage schedules using procaine penicillin with aluminum monostearate, two patients were found to have positive spinal fluid tests after therapy. One patient with secondary syphilis treated with a single injection of 900,000 units returned at 448 days with definite laboratory evidence of neurorelapse in all tests, and positive blood test. No spinal fluid examination had been made at the time of original therapy, nor had interim serologic examinations been made. Hence the blood serologic pattern could not be established. The other patient had been treated for primary seropositive syphilis with a single injection of 300,000 units. With no interim examinations and no prior spinal fluid examinations, he was found at 513 days to have a positive blood test, and in the spinal fluid examination the Kolmer test was strongly positive, total protein 42 mg. percent, cell count normal, colloidal gold not done.

Among our total patients treated with penicillin for early syphilis, a good proportion have been followed for 3 to 4 years, or longer. Central nervous system involvement has not been observed in any of those patients who have

shown normal post-treatment progress toward clinical and serologic negativity. There seems to be little reason to expect such involvement after an acceptable schedule of penicillin therapy, since we have observed relatively few cases of neuro-recurrence, regardless of the type of penicillin therapy.

Serologic Observation

In judging the success or failure of therapy, the ideal serologic follow-up of patients consists of an examination every 2 weeks, or at least every month, for the first 6 to 12 post-treatment months. In the evaluation of an experimental therapy, a battery of qualitative serologic tests and a quantitative test, performed regularly, is advantageous for observation. However, in a public health program or in routine therapy utilizing a schedule known to be effective, essential information may be gained from the regular use of one qualitative and one quantitative test performed preferably with a cardiolipin-lecithin antigen.

Failure vs. Reinfection

Re-treatment rates reported herein include patients who fail to attain cure as well as those who acquire a subsequent syphilitic infection, for in evaluating the various penicillin schedules it has often been difficult to differentiate between relapse and reinfection. It is practically impossible to fulfill all the traditional criteria for reinfection in penicillin-treated patients, because the antibiotic eradicates the infection so quickly that the patient is susceptible to reinoculation within a matter of months, days, or even hours after the termination of therapy. With the exception of certain penicillin schedules which were inadequate as to individual dosage, time interval between injections, or duration of therapy, the true failure rate has been very low. We believe that 60 to 80 percent of our re-treated patients actually had new syphilitic infections, either symptomatic or asymptomatic.

This belief has been strengthened by the results of extensive epidemiological, clinical, and laboratory studies of all re-treated patients. These studies were aimed toward determining

whether a patient with a true relapse will relapse a second time when re-treated with the same schedule of penicillin, or whether a favorable result following the administration of a second, identical course of therapy may indicate an asymptomatic reinfection. No report has been published, but the strong impression was gained from collected data that each reinfection can be cured by identical penicillin therapy; however, a true treatment failure will usually relapse again and again when re-treated with the identical schedule, but can be cured by an intensified one.

In patients with early infectious syphilis who have been successfully treated with penicillin, the serologic pattern may be expected to reverse to the negative state, usually within the first year. The rapidity of reversal is apparently dependent upon the stage and duration of the infection at the start of treatment and individual differences in immunological response. The unsuccessfully treated patient, when observation has been adequate, will usually show definite evidence of serologic relapse within 6 months following treatment; and clinical relapse may subsequently occur unless re-treatment is instituted promptly.

A patient with a suspected serologic relapse should be carefully observed to be sure that the sustained rise in titer is attributable to syphilis rather than to some acute intercurrent infection. Once a diagnosis of serologic relapse has been confirmed, penicillin therapy should be administered at once; otherwise, serologic progress to negativity may be delayed for months or even years.

Reinfections

Theoretically, a perfect schedule of therapy should result in 100-percent cure of all cases of syphilis. In such a situation, all reappearances of syphilis in the treated group would be reinfections. If it is correct that immunity to syphilis is a function of systemic exposure to the spirochete in terms of time and numbers of spirochetes, then patients whose original diagnosis was seronegative primary syphilis would have very little immunity and therefore would be readily susceptible to reinfection. Patients with seropositive primary syphilis would have

Table 5. Comparison at 12 to 15 months of cumulative re-treatment rates for an adequate penicillin schedule and for an inadequate schedule

Schedule of therapy	Stage of syphilis	Total cases	Number observed 12 to 15 months	Cumulative percent			Total cases re-treated
				Re-treated on basis of serology only	Clinical relapse	Probable reinfection	
Single injection of 300,000 units procaine penicillin with aluminum monostearate.	Seronegative primary.	38	19	0	0	0	0
	Seropositive primary.	64	34	7.5	1.8	3.5	12.7
	Secondary.	33	21	22.7	10.5	0	33.2
7,200,000 units of aqueous penicillin (200,000 units every 2 hours for 3 days).	Seronegative primary.	110	86	0	2.0	6.0	8.0
	Seropositive primary.	176	133	0	.6	2.6	3.1
	Secondary.	89	62	1.5	1.1	1.4	4.0

some immunity and hence be less liable to reinfection. Patients with secondary syphilis would have developed considerable immunity and would be still less liable to reinfection. Following this line of reasoning, it can be expected that the better schedules of treatment would show a higher re-treatment rate in the primary stage than in the secondary. A comparison of these factors in two of our schedules lends force to the argument. In table 5 are shown the cumulative re-treatment rates by stage of disease for a very successful schedule of treatment (7,200,000 units of aqueous penicillin administered in doses of 200,000 units every 2 hours) and for an inadequate schedule of treatment (a single injection of 300,000 units of procaine penicillin with aluminum monostearate). In the former schedule, the cumulative failure rate decreases from primary to secondary; whereas in the latter schedule, it increases from primary to secondary.

Summary

1. Penicillin, as the sole therapeutic agent, can cure early syphilis.
2. Adequate concentration of penicillin must be maintained in the host for at least 3 days.
3. Definite evidence of serologic relapse will usually develop in the unsuccessfully treated patient within the first six post-treatment months, and clinical manifestations may develop if this relapse is not promptly re-treated.
4. A more intensified regimen than the original schedule is usually necessary for successful re-treatment of clinical and serologic re-

lapse. Collected data indicates, however, that a reinfected patient may be cured by therapy identical to the original schedule, provided central nervous system involvement has not occurred.

5. Abnormal spinal fluid findings are observed in relatively few patients after an acceptable schedule of penicillin therapy for early syphilis. The clinician's suspicion of such involvement should be aroused by serologic relapse or resistance.

6. A single-dosage schedule of sparingly soluble penicillin in a satisfactory repository vehicle will eventually, in our opinion, be found to be therapeutically effective in early syphilis.

7. A successful schedule of penicillin therapy can be expected to show a higher cumulative re-treatment rate among early primary cases than among secondary cases; whereas an inadequate schedule of penicillin therapy will show a higher re-treatment rate among secondary cases than among primary cases.

Leading Causes of Death

The tables and charts in this report present final 1949 mortality data on leading causes of death for the first time. Previous release of final death rates for 1949 was limited to a selected list of 32 causes of death.

Meaning of Rank Order

One of the more popular ways of presenting causes of death is by rank order. It is often useful to know the first seven or ten leading causes, or that a leading cause of a generation ago has now dropped to a minor position. Rank order often lends itself to dramatizing a particular disease: "Fifty years ago cancer ranked eighth among the causes of death; now it is second only to diseases of the heart."

Those who use rank order should be aware of its pitfalls and limitations as well as its dramatic qualities. Rank ordering answers some questions but not others. For example, it does not adequately answer, "What are the most important public health problems?" There are of course many communicable diseases, now far down the list but potentially explosive, that have a public health importance far beyond their present low rank order.

The question that ranking answers best is, "What are the most frequent causes of death?" Even to this

(Continued on next page)

Diseases of early infancy	62.9
Tuberculosis, all forms	58.8
Influenza and pneumonia	49.0
Accidents	35.2
Chronic nephritis	30.0
Diabetes mellitus	18.6
Hypertension (without mention of heart)	14.1

question the answers are not fool-proof but depend on the specific list of causes of death from which the selection was made. At best, choice of a list is arbitrary, and it will often determine the rank of a particular cause—or whether it appears at all, since much depends on the way in which the various causes may be combined into broader categories.

Because of the interest in causes of death by rank and to promote uniformity in presentations of this kind, the Public Health Conference on Records and Statistics has recommended a rank-ordering procedure based on the Sixth Revision of the International Lists of Diseases and Causes of Death. This presentation is based on the "64-cause list" (table 1), designed for use in the National Office of Vital Statistics, with certain categories not ranked. These are indicated in the rank-order column of table 1 by "..."

Effect of Aging

Fifty years ago the leading causes of death in the United States were influenza and pneumonia, tuberculosis, and the group including gastritis, duodenitis, enteritis, and colitis. In 1949, influenza and pneumonia were in sixth place, tuberculosis in seventh place, and the diseases in the gastritis group had dropped to fifteenth place (table 1). These changes of course reflect, among other factors, the progress that has been made in the control of contagious disease in general, through such means as improved environmental sanitation and, more recently, the use of antibiotics.

Half the deaths in the United States are now caused by the cardiovascular diseases, of which the major component is diseases of the heart, accounting for more than a third of all deaths. Diseases of the heart are the leading cause of death for the population as a whole (see chart). The other principal components, vascular lesions of the central nervous system (chiefly cerebral hemorrhage) and general arteriosclerosis, rank third and eighth, respectively.

(See page 93)

Table 1. Deaths, death rates, and rank order for 64 selected causes of death, United States, 1949

[Deaths exclusive of fetal deaths and of deaths among armed forces overseas. Rates per 100,000 estimated midyear population excluding armed forces overseas. Numbers after causes of death are category numbers of the Sixth Revision of the International Lists, 1948.]

Rank	Cause of death	Number	Rate
	All causes.....	1, 443, 607	971. 7
7	Tuberculosis, all forms.....001-019	39, 100	26. 3
...	Tuberculosis of respiratory system.....001-008	35, 988	24. 2
...	Tuberculosis, other forms.....010-019	3, 112	2. 1
17	Syphilis and its sequelae.....020-029	8, 581	5. 8
38	Typhoid fever.....040	161	0. 1
...	Cholera.....043	0	-----
32	Dysentery, all forms.....045-048	1, 440	1. 0
37	Scarlet fever and streptococcal sore throat.....050, 051	486	0. 3
36	Diphtheria.....055	574	0. 4
35	Whooping cough.....056	727	0. 5
34	Meningococcal infections.....057	917	0. 6
43	Plague.....058	1	0. 0
29	Acute poliomyelitis.....080	2, 720	1. 8
42	Smallpox.....084	2	0. 0
33	Measles.....085	949	0. 6

12	Suicide.....	E963, E970-E979	16, 993	11.4
18	Homicide.....	E964, E980-E985	8, 033	5.4
41	Injury resulting from operations of war.....	E965, E990-E999	16	0.0

(Continued from page 91)

For the most part, the leading causes of death have changed because fewer deaths from infectious diseases are occurring in the early and middle years. Consequently, a larger proportion of the population now survives to the older years in which cardiovascular diseases and cancer occur most frequently.

The chart also shows rank order and estimated death rates for the same 10 leading causes in 1950. A major change was in the tuberculosis death rate, which dropped 16 percent, for an estimated decrease of 5,470 deaths. According to estimates for the first 8 months of 1951, this decline has continued.

Death rates for influenza and pneumonia for 1950 and 1951 increased slightly over 1949, probably as a result of the influenza epidemic during the late winter and early spring months. Rates for diseases of the heart and malignant neo-

plasms also increased in 1951 over 1950, though probably by no more than would be expected with aging of the population.

The four sub-charts reveal significant differences in the leading causes of death for white and nonwhite males and females. For perspective in interpreting the figures, the totals for all causes may be helpful.

All causes, 1949			
Group	Deaths	Death rates per 1,000	
White male.....	726, 169	11.0	
White female.....	542, 679	8.1	
Nonwhite male..	95, 122	12.4	
Nonwhite female..	79, 637	9.9	

Death rates for tuberculosis and vascular lesions of the central nervous system are considerably higher for the nonwhite groups than for the white. The rates for malignant neoplasms appear to be considerably lower; at least part of this difference is probably due to inadequate diagnosis.

Syphilis and sequelae are among the ten leading causes of death only for nonwhite males. For all four groups the rank and death rate for this cause are as follows:

Syphilis and sequelae, 1949

Group	Death rate per 100,000	Rank
White male.....	6.4	18
White female.....	2.0	21
Nonwhite male....	27.1	10
Nonwhite female..	11.7	12

Diabetes mellitus is among the ten leading causes for females but not for males:

Diabetes mellitus, 1949

Group	Death rate	Rank
White male.....	13.2	12
White female.....	21.2	7
Nonwhite male....	9.3	16
Nonwhite female....	18.6	9

The Practice of Public Health

PHR Conference Report

AGING

Public Health Has Chance To Enrich Added Years

Public health now has the opportunity to make worth while the years which have been added to life, Joseph W. Mountin, M. D., chief of the Bureau of State Services, Public Health Service, told the special general session on "Aging Challenges Public Health."

He pointed out that the goals of public health are to help older people remain productive members of society by preventing illness wherever possible, conserving mental and physical resources, and encouraging the maximum use of potential capacities. Despite an increasing interest in the problems of the aged, there is a certain reluctance on the part of professional workers to undertake any concrete programs, he felt.

Dr. Mountin called for a multidisciplined approach on a broad front. Already employers, labor organizations, educators, sociologists, administrators of welfare programs, and spiritual leaders are turning their attention to the problems of the aged. Public health must not only be an integral part of this nation-wide movement but must provide help and guidance in specific areas.

There are the health aspects of employment and retirement, Dr. Mountin noted, saying that more needs to be learned about work capacity and the physical and emotional status of the older worker. The health department, through the social and recreational clubs of older persons, has an opportunity to study the needs and desires of this group. He felt that health guidance and

counseling clinics can provide general guidance in such areas as diet, exercise, rest, physical appraisal, early detection of impairments, accident prevention, mental and emotional problems, and employment counseling.

The public health nurse can play a very strategic role in a health program for the aging because of her close contact with the family. Engineers may find it desirable to develop new standards for housing, taking into consideration the safety, comfort, and health of older persons. Perhaps the outstanding opportunities for fruitful work with older people are in the field of health education, Dr. Mountin said.

In our February issue the second half of this report of the APHA meeting will cover international health, statistical methods, epidemiology, and environmental health.

Health educators, more than anyone else, will be aware of the fact that we are working with, as well as for, older people.

Dr. Mountin concluded that health promotion in the later years depends more on the encouragement of wholesome individual and community attitudes than it does on the provision of any specific services. "By putting what we now know into usable form and disseminating it widely," he said, "and by reorienting our thinking and our services, public health can make great inroads against prejudice and inertia and help promote the sense of dignity and usefulness that, together with good health, can lead to a more satisfying life in the older years."

We Live Longer Than We Work—Suggests "Phased" Retirement

Man's life expectancy is increasing faster than his working life. He now lives relatively longer than he works or, in other words, in life's later years the period of nonemployment or retirement is increasing.

These factors were brought to the special session by Clifford Kuh, M. D., director of public health, Permanente Hospital, Oakland, Calif.

The most valuable point of view, said Dr. Kuh, is that man's working life is a continual adjustment of the man to the job and the job to the man. Age, like any other handicap, is purely relative. Rather than discharge the older worker as unemployable, he should be transferred to another job in the organization. As ways of keeping the older worker on the job, Dr. Kuh suggested "phased" retirement, or reducing the number of work days a week with advancing years; matching the job and the worker through placement techniques of job analysis. In favor of employing the older person are his skills, experience, loyalty, dependability, and his record for less labor turnover, fewer absences, and fewer accidents.

Housing for the Elderly

Housing problems for older persons arise from their relatively low economic status—the fact that they are left in homes too large and unsuitable for their needs, in which they remain because of pride and independence, said Joseph W. Willard, director of the research division of the Department of National Health and Welfare of Canada, in

discussing housing and living arrangements for older people at the special section.

He suggested as possible solutions to the problem: well-supervised boarding homes; community housing designed for the aged; renovation of old residences into single-family housekeeping units; or an annex arrangement whereby the older members of the family could maintain a separate home, yet still be close to their children.

Mortality Records of 16 Countries Superior to U. S.

Although no other country has consistently lower death rates than the United States, 16 countries have as good or better mortality records for the older age group (see chart), Louis I. Dublin, Ph. D., second vice president and statistician of the Metropolitan Life Insurance Company, reported to the statistical section. Dr. Dublin stated that the United States ranks among the best countries in the world with regard to longevity, yet this index of our leadership obscures some items in our health picture in which we fall behind other countries.

The United States has a distinct advantage in low mortality in childhood and early adult ages because of the gains which have been made in the control of infectious and communicable diseases. On the other hand, he pointed out, improvement in mortality rates toward the end of midlife has been relatively small, and in old age it has been almost imperceptible.

"Eating to Death"

Dr. Dublin places upon our way of life the blame for our reversal from a country of low mortality before midlife to one of comparatively high mortality thereafter, and upon the fact that as a Nation we have been blessed with an abundance and a variety of food with ample means to indulge our appetites. At least one-fifth of our adults are more or less seriously overweight. "A large number of our people are literally eating themselves to death," Dr. Dublin said. Insurance studies have shown that overweight in midlife is associated with higher than

APHA Conference Report

More than 4,000 professional workers in the ever-widening field of public health gathered in San Francisco to attend the seventy-ninth annual meeting of the American Public Health Association, the eighteenth annual meeting of the western branch of the association, and meetings of related organizations.

Delegates came from every State and Territory and from many foreign lands. They heard, and in many cases participated in, presentations by some 475 of their colleagues. But no one person attending the meetings could possibly take part in more than a very few sessions, no matter how far-ranging his interests. Yet, without doubt, those at the conference as well as those who remained at home want to be informed—as promptly as possible—of at least the main trends of discussions.

It was with these needs in mind that, through the cooperation of Dr. Reginald M. Atwater, executive secretary of the association, *Public Health Reports* undertook to provide a reporting service of the technical highlights of the entire 1950 meeting. These results were apparently generally satisfactory, and the Executive Board of the American Public Health Association urged that the practice be continued.

This is a news-type reporting of the highlights of many of the sessions. We have attempted to give the essence of the presentations, but by no means the complete story in each case. We have endeavored to reflect accurately the intent of each speaker although we have had to take somewhat extensive editorial liberties in the interest of brevity. The source of each report is stated and it must be clear that the author—not the Public Health Service—is the authority in each instance.

Our primary sources have been the advance abstracts, press releases, and texts available through the pressroom facilities of the association in San Francisco. This accounts for much of the selective character of the report. Material which was not available in some script form obviously could not be included. Reporting of informal panel-type discussions is, in consequence, incomplete.

We have dealt only with the scientific sessions of the meetings. Association business has not been reported, this being a function of the official journal. And no full papers, of course, are published. Complete texts of the leading papers have already begun to appear in the *American Journal of Public Health*, and others will appear in appropriate specialty journals.

The appreciation of the editors is extended to the many authors who provided us with texts and summaries of papers, and to the members of the Public Health Service staff who helped in collecting material.

average mortality, particularly from cardiovascular-renal diseases and diabetes.

Health Officer as Leader

Further, Dr. Dublin suggests that the high level of medical care in the United States has been prolonging the lives of persons impaired by earlier infections, who, in other countries, would die at an early age. Only a careful survey of the prevalence of such impairments in all countries can determine the validity of this assumption.

The situation of the increasing proportion of older persons in the population presents an inviting opportunity for the health officer to raise the level of health in his community, concluded Dr. Dublin. He can assume more leadership in accident prevention, in the early detection of degenerative diseases, and in health education programs in nutrition and in habits of personal hygiene.

ADMINISTRATION

Health Aims Are Citizen Responsibilities Also

The American Public Health Association evaluation schedules for appraising local health services are a valuable technical tool for health personnel in program supervision and control, but they are too complex to be appropriate for general publication, the health officers' section was told by V. A. Van Volkenburgh, M. D., assistant commissioner of the New York State Department of Health.

Evaluation data are a fundamental necessity in any health department program, said Dr. Van Volkenburgh, but wherever possible citizens should be led to discover for themselves the health needs of their communities and how these needs may be best satisfied. The desired goal for community health projects is citizen responsibility, not health department responsibility alone, he continued.

Dr. Van Volkenburgh said that a simple nontechnical form of health survey should be utilized for reporting results to the general public. He

Number of Countries With Age-Specific Death Rates Lower Than United States

Postwar experience of a total of 17 countries of western Europe and English-speaking countries elsewhere

—Chart from Metropolitan Life Insurance Co.

felt that surveys requested and participated in by citizens' groups, with the technical aid of the health department, are usually most meaningful to the public.

Central Service Agencies

The growing need for the services of the nonmedical administrator in public health organizations was discussed by two panels conducted by the Association of Business Management in Public Health. One panel dealt with the topic, "Is public health unnecessarily restricted by central service agencies?"

Moderator of the panel was Robert G. Webster, chief of the division of administration of the California State Department of Public Health. Other discussants were Pierce H. Fazel, chief administrative analyst with the California State Department of Finance; H. Neil Graham, public health representative, Federal Security Agency Region X; James C. Malcolm, M. D., health officer of

Alameda County, Calif.; Henry C. Schumacher, M. D., consultant in mental health activities, Federal Security Agency Region X; and Clifford C. Shoro, director of the office of business administration, New York State Department of Health.

The discussion developed the point that many central service agencies are inclined to dictate aspects of programs in some situations. The panel appeared to accept the view that the central service agencies should determine what a program would cost, should handle the budgetary presentation and operation, and should provide consultation on any potential fiscal or administrative problems.

The program director has the basic responsibility for the program and thus must be prepared to explain what has been done and what is proposed, the discussion developed. He should be able to prescribe, realistically and reasonably, the tools which he requires for his work.

Skilled Administrators

The second panel was a sequel to the discussion, held in St. Louis in 1950, of the role of nonmedical administrators. Moderator Murray R. Nathan, assistant director of the office of medical defense of the New York State Department of Health, as a basis for the discussion, outlined the widespread belief that there are many important duties in large public health agencies which persons trained in administration, but without medical training, can effectively perform.

The panel consisted of J. B. Askeew, M. D., health officer of the city and county of San Diego, Calif.; Carl E. Buck, Dr. P. H., professor of public health practice at the University of Michigan School of Public Health; Gordon R. Cumming, chief of the bureau of hospitals, California State Department of Public Health; Evelyn Flook, chief of the program evaluation and records section of the Division of State Grants, Public Health Service; and Hollis S. Ingraham, M. D., deputy commissioner of the New York State Department of Health.

Many public health organizations have developed to such a size that if all administrative duties fall upon the medical director he is unable to direct the basic program as he should. While there is a lack of administratively trained personnel, the management job continues to grow as a responsibility and requires a separate person of status.

While the need for an administrator has been present in many departments for a long time, the need has not been interpreted nor understood by many health officers, the panel felt, and it often is only under the burden of voluminous paper work that the need becomes apparent.

Community Health Councils

One of the increasing points of emphasis in 1951—in health as well as in other fields—is the recognition of the importance of the community as a whole with its family and individual units, Ira V. Hiscock,

Sc. D., M. P. H., chairman of the Yale Department of Public Health, remarked before the National Conference for Health Council Work.

Reviewing the recent growth and present place of health councils, Dr. Hiscock pointed out that "in occupying a place of central responsibility in the planning process, a council needs to be representative of community forces and to insure that so-called operating agencies share responsibility to participate in the community organization, the study, and the planning process."

The extent of this participation may be influenced by the politics, program, budget, and functioning of given agencies, as well as limited by the kind and quality of staff available, Dr. Hiscock noted. The broadened horizons and increased flexibility of approach to joint studies of cooperative programs among some national agencies, he said, especially as they relate to local partnership projects in central planning and coordination, are favorable symptoms.

"In turn," the Yale professor said, "commendable trends are noticeable in some fund raising quarters to recognize the fact that more than dropping money in a slot is necessary to produce constructive research and to apply and interpret the benefits of scientific knowledge."

Professional Education

"A comprehensive professional education and training program is one of the basic objectives of any cancer control program," asserted Paul R. Gerhardt, M. D., director of the bureau of cancer control, New York State Department of Health, in speaking before the Public Health Cancer Association.

Dr. Gerhardt described the extensive and comprehensive professional education and training program for cancer being carried out in New York. The activities include all professional groups and consist of distribution of literature, periodicals, and professional movies, and the provision of lectures, teaching days, tumor clinic consultants, re-

fresher courses, and postgraduate training. The program is in cooperation with the State medical society and cancer association.

The physician is "the one individual upon whose shoulders perhaps rests the greatest responsibility," Dr. Gerhardt pointed out. "On his efforts to recognize precancerous lesions, to suspect and diagnose cancer early, to render adequate treatment, and to secure competent consultation depends frequently the life or death of the individual."

Manpower Needs in England

With expanded manpower needs of Great Britain's National Health Service, considerably more health workers are needed, and this, combined with a shortage of young people, requires drastic steps, J. Greenwood Wilson, M. D., school medical officer and medical officer of health, city and port of Cardiff, Wales, told the health officers' section.

The British medical officer of health advocated the following steps: training the individual worker for multiple jobs—such as combining the jobs of the public health nurse, the midwife, the health educator, and the social worker; removing the public health nurse from clinics and providing domestic help to assist those with chronic and acute illnesses at home; emphasizing child health; making sure sanitarians are being utilized wisely; training physicians to enable them to give spot care in civil defense; and training the population in first aid techniques to relieve professional manpower.

REHABILITATION

Time Lag Must Be Cut, Knowledge Put To Work

With a tide of chronic disability threatening to engulf us medically, socially, and economically, we must reduce the time lag between our available knowledge of the problem and its application to those whom it would benefit, Mary E. Switzer, director of the Federal Security Agency's Office of Vocational Reha-

bilitation, stated before the industrial hygiene, medical care, and public health nursing sections.

Miss Switzer pointed out that statistics of the Liberty Mutual Insurance Company's rehabilitation center in Boston show the average time between injury and referral to the center to be 6.4 months. A study of the Federal-State program shows that in 4,400 cases the time lag between injury and referral averaged 7 years. This is a serious waste for the individual, the employer, and the country as a whole, she said.

Much depends on placement procedures, she added, citing a survey by the Public Health Service which showed that coordinated hiring practices between medical, safety, and personnel departments produced much lower rejection rates for physical impairment than when rigid standards were adhered to on a mass basis.

Disabled Men Work Again

Gains in human values and in dollars far exceed the cost of providing rehabilitation services, Stanwood L. Hanson, assistant vice president of the Liberty Mutual Insurance Company, emphasized in reporting his company's interest and work in this field.

The insurance company became interested in rehabilitation as a matter of sound business principles, said Mr. Hanson. Research into the problems of reducing length and severity of accident disablement revealed errors in diagnosis and in psychological handling of individuals. These research efforts culminated in the establishment of a rehabilitation center in Boston in 1943 and one in Chicago in 1951.

Over 2,000 persons have been treated at the Boston center, Mr. Hanson said. Approximately two-thirds of them have returned to productive employment. Some 200 major amputees are wearing artificial limbs successfully; three-fourths have been restored to jobs.

Service at the Boston center includes physical, occupational, and recreational therapy, and possible needs for vocational re-education or

appropriate employment are also considered, he said. Placement problems are handled by rehabilitation nurses, trained to counsel seriously injured workers in coordinating their entire process of rehabilitation.

The rehabilitation work is carried on without cost to the injured worker, continued Mr. Hanson. He said the average cost of the 400 cases during the past year was \$480 a case and that his firm feels this to be a profitable investment.

Problem Follow-Up

Full employment cannot be a realistic rehabilitation goal for every disabled person, Bernard D. Daitz, M. S. P. H., special assistant for tuberculosis rehabilitation of the Veterans Administration, emphasized to the rehabilitation workshop session of the medical care section. Sheltered or home-bound employment, or mere capacity for self-care, may be the most practical goals in the rehabilitation of some disabled persons, said Mr. Daitz.

Attempted rehabilitation of any person is impractical, he continued, unless a thorough follow-up and evaluation process is also conducted. These are inseparable in the rehabilitation process, for without follow-up, evaluation is impossible and without evaluation, follow-up is meaningless, he said. The mere healing of an amputee's stump or the arresting of a disease is not enough, he pointed out. If the amputee discards his prosthetic device because it is useless in his work, or if the tuberculosis patient becomes only a health department case entry, rehabilitation work has been in vain.

Statistically complete case histories adequately reflecting services required by the patient, the services actually supplied him, and the end results achieved, are of vital importance to the rehabilitation process, Mr. Daitz stated. Only the routine production and review of such records will enable the rehabilitation worker to assess the results of his work and to develop his field to a level of professional maturity, he concluded.

Case Services

A unified, cooperative team of medical specialists and education and vocational training specialists is required to rehabilitate the handicapped person, the rehabilitation workshop of the medical care section was told by Sydney S. Norwick, M. D., M. P. H., regional medical consultant of the Federal Security Agency's Office of Vocational Rehabilitation in San Francisco.

Such a team is needed in rehabilitation, said Dr. Norwick, because the family doctor can no longer keep abreast of all new medical developments, nor can he maintain detailed knowledge of his patient's family and psychological needs, or of all the vocational possibilities in the community. To evaluate properly the total potentialities of the handicapped person, he continued, it is necessary to utilize information from multiple sources, such as nurses, physical and occupational therapists, laboratory and X-ray examinations, and results of skilled interviews and evaluations of personal, psychological, and social attitudes and situations.

This evaluation must consider the attitude of the family and of the community toward the individual as well as his feelings about them, Dr. Norwick said. He added that rehabilitation is incomplete unless the individual is made to feel that he has some means of regaining status in the minds of his family and his community. Economic and social factors are also important, he said.

Dr. Norwick emphasized that physicians must not only evaluate medically the patient's condition but also interpret to the patient, his family, and other members of the rehabilitation team precisely how his disability handicaps him or is likely to handicap him in the future. The physician must also share in the detailed planning for physical restoration services, including the provision for all necessary convalescence and follow-up services such as prosthetic appliances and the training of the individual in the use of them, he added.

OCCUPATIONAL HEALTH

MEDICAL CARE

Health Service Needed In Small Plants

The health professions, labor, and management are confronted by the basic job of promoting the establishment of health programs in small plants when they are inadequate or nonexistent, Seward E. Miller, M. D., chief of the Public Health Service's Division of Occupational Health, told the industrial hygiene and medical care sections.

Dr. Miller emphasized, also, that helping the worker to achieve maximum health and productivity—through rehabilitation, programs in human relations, or provision of general diagnostic and preventive services—calls for the combined efforts of the health and related professions. "It is not enough," he said, "to tell the employee that he should see a doctor; instead, every opportunity must be sought to make the plant medical department a vehicle by means of which the worker and the community's public and private health resources are brought together."

Emphasize Optimum Health

Industrial medicine offers the opportunity to emphasize the attainment of optimum health rather than the curing of established illness, Dr. Miller continued.

Industry realizes that mental and social as well as physical factors must be considered if maximum health and productivity are to be achieved. The fact that at least one-third of all sickness absenteeism in industry is caused by emotional disturbances is causing concern to both management and labor, Dr. Miller reported. For these reasons, industry is showing promise of taking the lead in prevention and relief of occupational factors associated with mental, emotional, and related disorders among its workers.

Rehabilitation of persons kept out of the labor market by injury or illness and guidance as to sources of assistance are other areas in which the physician is alining himself with the social scientist.

Cooperation between health and allied agencies is necessary to insure that the worker carries out the recommendations made after pre-placement and periodic examinations. Referral and follow-up procedures need to be strengthened, he said, and the services offered by pre-paid medical care and hospitalization plans should be expanded.

In 1975, the number of workers over 45 years of age is expected to be twice the 18-percent figure of 1900, Dr. Miller pointed out, saying that even though these workers remain healthy and efficient, fatigue and a certain amount of chronic disease will necessitate maintaining careful checks on their health.

Principles of Service

Herbert K. Abrams, M. D., chief of the bureau of adult health, California State Department of Public Health, told the industrial hygiene section that the work of a governmental industrial hygiene agency includes more complex activities than the control of occupational diseases. "Investigation of occupational health hazards, measures for their prevention, promotion of good health services in plants—these are the cardinal elements of the program," he said. "But in the background of all of these and directly bearing on the success or failure of the program are the more complex social and economic factors; for example: attitudes of labor and management to health measures, . . . to each other, and to the governmental agency."

Five basic principles must be observed by governmental units, according to Dr. Abrams: (1) the primary responsibility to safeguard the health of workers; (2) unbiased technical work and policies; (3) authority in speaking on health hazards and the adequacies of measures for protecting employee health; (4) intelligent interpretation of the program to labor, management, and the health professions; and, as the major objective (5) to conduct studies to improve the previous methods used by the plant as well as those used by the agency.

No Magic In Fee System, But Service Must Result

"No method of payment possesses the magic power of producing high quality of service," Franz Goldmann, M. D., associate professor of medical care of the Harvard University School of Public Health, maintained before the medical care section after reviewing the problems and methods of payment to physicians in medical group practice.

Missionaries by far outnumber mercenaries among group-care physicians, Dr. Goldman pointed out, but payment to physicians must encourage adequate service in health and sickness, he emphasized.

The physician expects compensation which recognizes the long period required for his education, the experience and skill acquired after graduation, and the value of his service to individuals and to the community. The agency administering group funds wants quantitatively and qualitatively adequate service at the least cost consistent with high standards, he said.

Mine Workers Fund

In the discussion following Dr. Goldmann's remarks, Dr. John Newdorp, assistant to the executive medical officer of the United Mine Workers of America Welfare and Retirement Fund, described the policy and experience of that organization. The fund has about 2,000,000 beneficiaries, and care is provided on a fee-for-service basis. The decision to use fee-for-service was based on the large numbers of persons involved, the preference of physicians for this method of payment, and the urgency in getting started, Dr. Newdorp reported. No formal agreement is made with physicians and no fee schedule has been adopted. This method of payment provides geographic and qualitative flexibility and precludes bargaining. Bills which appear to be unreasonable are reviewed by the area medical officer.

Crippled Children's Program

Dr. Marcia Hays, chief of the bureau of crippled children's services, California State Department of Public Health, stated that the fee-for-service method of payment was the only feasible one for a service such as that provided under the crippled children's program. A great deal of work is entailed in maintaining fee schedules. Fees are negotiated with specialty groups. These negotiations are facilitated by the fact that beneficiaries are children. Some flexibility is allowed for exceptional cases. The careful maintenance of the fee schedule helps to reduce administration to a minimum, she reported.

California Physicians' Service

Dr. Albert E. Larson, medical director of the California Physicians' Service, described payments made by that organization, which is served by some 11,000 physicians. Fee schedules are developed by consultation with physicians and are reviewed every 2 years. A questionnaire concerning fees was sent to every physician in California, and an average fee schedule is being established. The organization does not wish to set payment levels to those characteristic of the low-income group, Larson said. Subscribers get about 50,000 services a month in office, home, and hospital. Bills are submitted by code. The administrative cost is about 3½ percent. Bills are reviewed by the medical policy committee of the board of trustees' local medical review committees.

Vocational Rehabilitation

Dr. Thomas B. McKneely, chief medical officer of the Office of Vocational Rehabilitation, Federal Security Agency, described its policies for payment for physician services. State plans must provide schedules of fees as part of the procedure for satisfying Federal requirements for approval, and full payment is made

for medical services. Rates must not be in excess of those paid by other agencies.

Professional advisory committees are used in devising fee schedules. Fee-for-service payments have been adopted because of the nature of the program, Dr. McKneely reported.

Health Insurance Plan

Dr. Edwin F. Daily, deputy medical director of the Health Insurance Plan of Greater New York, indicated that the plan now has an enrollment of some 250,000 beneficiaries, with an average premium payment of \$23.33 per year.

More than \$7,000,000 a year is paid by the plan for medical services—almost equal to the amount paid by Blue Shield for 10 times the number of subscribers. Dr. Daily attributed the difference to the fact that HIP provides a comprehensive medical service whereas the Blue Shield program has many restrictions.

Payments to medical groups are made on a per capita basis, and the group determines the distribution of its income among capital expenses, administrative costs, and payments to physicians. Methods of payment to physicians are determined by each individual group, he said.

Permanente Hospital and VA

Dr. J. P. FitzGibbon, medical director, Permanente Hospital, Oakland, Calif., indicated that the fee-for-service method of payment did not work and that the salary type of payment is now in effect. Dr. James C. Harding, assistant chief medical director for out-patient service, Veterans Administration, indicated that at the 132 Veterans Administration hospitals and 110 out-patient clinics physicians are paid on a salary basis. In the home town service of the Veterans Administration, payments are made on a fee-for-service basis using a fee schedule devised by the Veterans Administration. In addition, clinical consultants to the Veterans hospitals are paid at a daily rate.

Puget Sound Cooperative

Dr. Erwin S. Neiman, director of preventive medicine, Group Health Cooperative of Puget Sound, Seattle, stated that physicians in the group are paid a full-time salary. Home, office, and hospital care is provided. There are no extra charges. Some 30,000 beneficiaries are served by a group of 27 physicians. Administrative costs are low. Variations in salary are based on differences in degree of responsibility carried, Dr. Neiman said. The medical staff policies, the quality of service rendered, and staff meetings are valuable in maintaining standards. He pointed out that some system of reward for meritorious service would be desirable. Bonuses are now distributed equitably among the medical staff.

More Under-Utilization Than Abuse of Prepaid Service

From the viewpoint of preventive medicine, there is under-utilization rather than abuse of service in prepaid medical plans, S. J. Axelrod, M. D., associate professor of the University of Michigan School of Public Health, and Robert E. Patton, M. P. H., biostatistician of the New York State Department of Health, reported to the medical care section. Their study of the Windsor Medical Services of Canada revealed that 39 percent of the subscribers saw no physician during the 12-month study period. Other findings were:

Only 1,500 of more than 100,000 subscribers chose the limited surgical rather than the comprehensive physicians' service contract. This preference is striking in view of the negligible interest in comprehensive coverage attributed to Blue Shield members, Axelrod and Patton felt.

Of subscribers who saw physicians, 36 percent saw one, 15 percent saw two, and 10 percent saw three or more physicians. Only 1 percent saw four or more practitioners.

There were only 42 night calls per 1,000 subscribers during the study year, although no extra charge is

made for such calls. Windsor Medical Services has waiting periods for preexisting conditions, but the study did not show that this was necessary, the authors said. The 21 percent of subscribers who joined during the study year accounted for 9 percent of the total participant months.

California's Disability

Payments Total \$97 Million

Between December 1946 and the end of June 1951, California paid 97 million dollars in disability insurance, and since January 1950, 4 million dollars has been paid for hospital benefits, Herbert M. Wilson, chief of the division of disability and hospital benefits of the California Department of Employment, reported to the industrial hygiene and medical care sections.

California was the second State to incorporate a disability insurance program in its unemployment insurance for victims of nonoccupational illnesses and injuries, and has added hospital benefits since January 1, 1950. The California law permits "contracting out" under private plans offered by insurance carriers. Employees pay all costs of disability insurance and hospital benefits through a 1-percent tax on their wages. The program is administered by a lay staff of claims examiners reinforced by a medical director and staff, he said.

1950 Social Security Changes

Affect Care of Needy

That "health and welfare are—or should be—in business together," is the thesis of the draft statement on tax-supported medical care for the needy, jointly prepared by the American Public Health Association and the American Public Welfare Association, Lucille M. Smith, public health administrator of the Division of Public Health Methods, Public Health Service, told the medical care section.

The joint statement provides facts needed to enable both health and welfare agencies to discharge the responsibility for which they each

have special competence, she said. The most timely, she felt, was the review of provisions of the 1950 amendments to the Social Security Act that directly affect medical care for needy persons, and the discussion of how Federal funds for medical service for recipients of assistance can be used.

The joint committee agreed, Mrs. Smith pointed out, "At this time no single pattern of responsibility for medical care to needy persons is either possible or desirable. . . . Whatever the pattern of administrative responsibility, cooperation between health and welfare departments is essential to effective use of public resources. Through joint planning, duplication and waste can be avoided, gaps in service can be filled, and the future development of programs can be placed on a sound basis."

Antibiotics, Not Surgery, Cutting Appendicitis Toll

"Looking backward from today's vantage point, it seems unlikely that surgery alone contributed much to the reduction of appendicitis mortality," Paul A. Lembecke, M. D., associate professor of public health administration of the Johns Hopkins University School of Hygiene and Public Health, told the medical care section.

"Substantial reduction in appendicitis mortality appears to be attributable almost entirely to treatment with the sulfonamides and other antibiotics," and "whether surgery is needed in addition to antibiotic treatment is still an open question," he said.

Dr. Lembecke expressed these views in connection with a study of appendectomy rates as a segment in a study of the quality of medical service. "The true measure of quality must be based not on how well or how frequently a medical service is given, but on how closely the result approaches the fundamental medical objectives of prolonging life, relieving distress, and restoring function," he maintained.

The study covered 860,000 persons in 7,400 square miles of western New

York served by 33 general and 14 special hospitals. Combined crude primary and secondary rates for appendectomies in 1948 were 5.43 per 1,000 population, or about one-third of the average birth rate for the past 20 years. This would suggest that one-third of the population would have appendectomies sometime during their lives, he reported.

FLUORIDATION

Dental Caries Reduced by Fluoridation

Dental caries in children can be reduced 60 to 70 percent by the use of fluorine-treated water, Dr. Hollis Ingraham, M. D., deputy commissioner of health of New York, reported to a joint session on fluoridation of the dental health, engineering, and health officers sections, delivering the paper of his chief, Dr. Herman Hilleboe. Results of a 4-year study in Newburgh, N. Y., where the effectiveness of fluorine-treated water on tooth decay was tested, showed that the number of lost first molars decreased by 60 percent and untreated, decayed first molars decreased by 68 percent.

Dr. Ingraham predicted that if this trend continues, a point may be reached where, with the present complement of practicing dentists, such caries as may occur can be treated, and tooth mortality and untreated caries may be reduced to a negligible level.

Dr. Ingraham also commented on the low cost of fluoridation, stating that estimates indicate a cost to each person of only 5 to 15 cents per year. He estimated that if a person lives to be 70 years old, he may expect a reduction of 67 percent in tooth decay, for a total cost of \$2.10.

Dentists Have Four Duties

The dentist's responsibilities in the fluoridation of public water supplies are fourfold, according to Robert A. Downs, D. D. S., chief, public health dentistry section, Colorado State Department of Public Health.

Since it is obvious that the solution of the dental caries problem is hopeless if it is attacked from the

angle of restorative dentistry alone, the first and direct responsibility of the dentist is to promote fluoridation. Second, he will also be called upon to provide factual information on cost, methods, possible harm, and results.

Because of the widespread publicity given to fluoridation programs, many communities agitate for fluoridation without knowing whether or not their water supply contains the recommended concentration of fluoride. The third responsibility of the dentist, therefore, is to establish a baseline and have chemical analyses made of the water supply to determine whether fluoridation is necessary. Finally, Dr. Downs pointed out, the dentist has the responsibility for evaluating the effects of the program, after a sufficient period of time has elapsed.

Engineers Are Key Men

The success of fluoridation installations will depend primarily on the efforts of engineers, said Franz J. Maier, senior sanitary engineer of the Division of Dental Public Health, Public Health Service. It is the engineer's responsibility to determine how much fluoride should be added and which compound should be used. He must also determine which type of feeder to use and how the fluorides should be applied. The protection of the operators and the control of the fluoride concentration are also problems that must be solved.

Mr. Maier pointed out that a fluoride concentration of 1.0 ppm is optimum, though it will vary in some parts of the country. At present three preferred compounds are used: sodium fluoride, sodium silicofluoride, and hydrofluosilicic acid. Choice of the compound will depend upon the size of the treatment plant, storage space, and the type of feeder equipment used. Protective devices and careful handling will eliminate hazards to operators. Mr. Maier concluded that a periodic fluoride determination of representative water samples is necessary to maintain a constant check of the accuracy of the fluoride concentration.

Wisconsin Experience

To date a total of 63 communities with a population of 657,044 are fluoridating their water supplies, reported O. J. Muegge, State sanitary engineer, Wisconsin State Board of Health, in describing the Wisconsin experience in applying fluoride to water. Twelve water supplies have an adequate fluoride content. When pending installations, including that of Milwaukee, are placed in operation, 69 percent of the population of the State served by water systems will have fluoridated water.

Mr. Muegge noted that the Wisconsin experience with controlled fluoridation of communal water supplies has been most favorable. Dental surveys have shown that caries control is comparable to that of communities with natural fluorides. Personnel in even small communities are capable of operating equipment and performing control determinations. Problems of incrustation and corrosion can be met and hazards to operators minimized.

HOME ACCIDENTS

"Immunize" Children With Protection and Education

If protection is regarded as passive immunization and education as the active component, it can be shown that, with proper boosters, children can be immunized against serious accidents, Harry F. Dietrich, M. D., of the Beverly Hills Clinic told a session of the subcommittee on accident prevention of the committee on administrative practice.

Parents and all others concerned with child care must be acquainted with a practical theory of accident prevention. "The time spent on manners and mummery, cleanliness and curls, and bowels and bladder might better be spent on education in safe behavior," Dr. Dietrich maintained. "It is not that I object to pretty, clean children, well mannered in eating, eliminating, and entertaining—it is only that I do not like to see them dead of accidents."

Protective and educational measures must be reciprocally related and varied according to the child's age, he said. During the first year of life, 100-percent protection must be provided; by 5 years of age principal reliance must be placed on what the child has experienced and has been taught, Dr. Dietrich felt.

Rally Public Support

Safety has not been built into the home and cannot be enforced as it can in traffic, Joseph M. Kaplan, of the Los Angeles chapter of the National Safety Council, reminded the subcommittee session.

"Home safety for some reason has been an orphan in the society of safety problem children. It has been shunted aside in favor of its more dramatic family member, traffic safety," Mr. Kaplan said. Home safety, however, is almost exclusively an educational problem, and "rallying public support for a home accident prevention program is our only hope if we are to do something other than wring our hands in despair," he maintained.

Study Fatal Accidents To Get Representative Picture

"A study of reported fatal accidents will give a more representative picture of the accident problem in a community than will an investigation of nonfatal cases," I. Jay Brightman, M. D., Isabel McCaffrey, and Leonard P. Cooke, of the New York State Department of Health, maintained before the home accident session.

The general universality of death reporting in many States will yield data on all cases regardless of economic status, allegiance to cults, and local differences in degrees of utilization of medical, nursing, and hospital facilities, Dr. Brightman and associates said.

Reporting on a study which goes back to 1932, Dr. Brightman and his colleagues found that accidents of all types were the fifth cause of death

at that time in New York State, with a rate of 85 per 100,000. The overall rate has dropped to 67, but the home accident fatality rate rose by about 14 percent from 1932 to 1936 and has since remained steady.

The death rate from home accidents among children less than 5 years of age does not seem to have changed materially, Dr. Brightman reported. However, there have been definite declines in the age groups from 5 to 64 years. The fatality rate for those 65 and older has remained constant from 1936 to 1948. This group, he pointed out, contributes about 65 percent of all the home accidents and therefore carries a great deal of weight in the trend for all ages.

This fact, coupled with the growing proportion of older persons in the population, suggests that "the total number of fatal home accidents may be expected to increase constantly unless effective preventive measures are developed," the New York group said.

Accidental CO Deaths

Accidental domestic deaths from carbon monoxide poisoning constitute a serious health problem which warrants an intensive investigation into the causes and circumstances of these deaths and the establishment of effective preventive measures, the industrial hygiene section was informed by Jerome Trichter, assistant commissioner in charge of environmental sanitation, New York City Department of Health, and Milton Helpern, M. D., deputy chief medical examiner, Office of the Chief Medical Examiner, City of New York.

Defective domestic gas equipment and appliances were cited as a major cause of fatal accidents. There were 113 deaths from such causes in New York City in 1950. Special attention was called to the increasing incidence of single and multiple fatal and nonfatal poisoning cases due to the inhalation of carbon monoxide from improperly operating gas flame refrigerators.

Legend

—Adapted from Trichter and Helpern.

Mr. Trichter and Dr. Helpern revealed that a survey of 20,000 New York City homes showed that a high percentage of the homes contained defective gas appliances.

They outlined the control and prevention measures taken in New York City and urged that the full resources of all official agencies, periodical inspections and servicing, health education, and newspaper publicity be used to combat the problem of carbon monoxide deaths. Health departments and medical examiner's offices should assume leadership in this program, they said.

Epidemiological Techniques

Home accidents are now regarded as a disease in the realm of preventive medicine and public health, John E. Gordon, M. D., Helen L. Roberts, M. D., and Antonio Fiore, M. D., from the Departments of Public Health Practice and Epidemiology of the Harvard University School of Public Health, said.

The changed attitude toward home accidents, which no longer will accept bad luck or chance as an excuse for death and crippling, is also responsible for a new commu-

Five combination services in cities in different geographic areas were evaluated in the National Organization for Public Health Nursing study.

The study included analysis of questionnaires filled in by each agency, Personal interviews with private physicians, health officers, staff nurses, voluntary association board members, community chest officials, and those who had received nursing care were evaluated. Administrative practices of the agencies were also considered in the study.

None of the agencies had sufficient personnel to meet currently accepted standards, Miss McIver stated. However, all were convinced that the services of each nurse were utilized more economically under the combination plan.

Cancer Nursing

The nurse who is well prepared in cancer nursing and in its public health aspects can be a powerful adjunct to the medical profession in promoting cancer control programs, the Public Health Cancer Association heard from Rosalie I. Peterson, R. N., of the National Cancer Institute, Public Health Service.

Broad educational preparation is essential for all nurses if they are to function in control programs as well as in hospital services, Miss Peterson pointed out. She reported that some of the problem areas are patient management in a cancer clinic, teaching the patient self-care, planning for continuity of care, and community planning for a cancer control program.

A monograph on cancer nursing for use in the basic professional

nursing curriculum has been developed, Miss Peterson reported.

Children's Eye Problems

Public health has made major contributions to saving sight, but there is still no justification for complacency, Helen E. Weaver, R. N., M. P. H., consultant in nursing activities, Society for the Prevention of Blindness, stated in a session of the society.

Parents should be encouraged by the public health nurse to have an eye examination made by a competent eye specialist during the infant's early life, she continued. Before the child begins school a complete eye examination is again desirable. Screening tests must also be considered an integral part of the school health program, Miss Weaver emphasized.

Public Health in Civil Defense

KANSAS FLOOD

Enemy or Nature—Aims in Emergency Are Same

A catastrophic flood demanded herculean efforts—and received them—when Kansas rivers rose to a historical peak. Sixty percent of the average annual rainfall fell in May and June; the remaining 40 percent, in a 3-day period beginning on Friday, July 13, Dwight F. Metzler, chief engineer of the Kansas State Board of Health, said in reporting to the engineering section and the conference of State sanitary engineers on the emergency sanitation lessons derived from the 1951 flood in Kansas.

Water and food supplies and sewer systems were disrupted. The handling of refuse, the disposal of corpses (16,000 animals in this case), the control of flies and other insects, emergency housing, and rehabilitation became major problems. Yet, the only known disease outbreak, Mr. Metzler noted, occurred, not at mass-feeding centers where local and State health department

sanitarians made frequent checks, but among a utility crew using a common drinking cup!

The lessons learned in Kansas were many and would apply to other types of disaster, either natural or man-made, Mr. Metzler declared.

A preplan should include: a director to coordinate all sanitation measures and to channel all assistances; a classified list from which to draw a committee of technical persons, who should be given adequate authority; a central information service to keep in close contact with the people, to avoid panic; adequate communication and transportation systems depending upon a mutual aid program in which mobile equipment may be supplied by unaffected communities within and without the State; a map of emergency sources of water supply available to key personnel.

In addition, Mr. Metzler felt, there should be built up a larger reserve chemical feeding capacity at water plants, provision for more water storage capacity to be located far above the possible high-water area, establishment of a fund to purchase

small supplies ("A few pairs of boots or several hand sprayers were more difficult to purchase than four plane-loads of DDT"), valves on all drains and pipes through dikes of every existing waterworks; placement of new construction high enough to prevent leakage into clear wells.

Federal Services Directly Aided States in Flood Crisis

Planning to meet health emergencies on a national scale is a full-time, continuing job, M. Allen Pond, M.P.H., chief, Engineering Resources Division, Public Health Service, told the joint meeting of the conference of State sanitary engineers, the conference of municipal public health engineers, and the engineering section. "Whatever the cause of the emergency, the aims of those who meet it are the same—to confine the damage, to restore order, and to rehabilitate the people and the facilities affected," he said.

Mr. Pond illustrated his remarks by the recent flood. The resources of two great States, he said, proved inadequate to cope with the health

problems that rose with the rivers in Kansas and Missouri. The yeoman efforts of State and local health authorities resulted in confining the damage so that public health measured in terms of morbidity and mortality did not suffer during or after this disaster. But, even in a comparatively slow-developing emergency involving no serious casualties to health service personnel, or to the public generally, the State health authorities requested aid, and assistance had to be assembled from points east, south, and southwest. The fact that assistance could be made available immediately, Mr. Pond declared, is traceable to the disaster-planning activities of the Public Health Service Communicable Disease Center. From New York, Georgia, Mississippi, and Texas immediate help came in the form of personnel, equipment, and supplies.

Three Action Steps

First, estimates of damage and necessary emergency action were made by the State health authorities. Plans were made on the scene and put into immediate effect. Second, restoration of basic utilities and services was made as rapidly as possible. The third step was rehabilitation.

The President of the United States, invoking the provisions of a newly enacted law (P. L. 875, 81st Cong.), asked Congress for and was granted funds to assist the people of the area to meet the crisis. He designated the Housing and Home Finance Administrator to coordinate Federal flood relief, Mr. Pond said.

The Food and Drug Administration personnel assigned to the area placed an embargo on all food, beverages, drug and cosmetic stocks, and supervised salvage operations. This action confined the results of the damage.

The Department of Agriculture Extension Service helped to clean up farms and to protect animals against disease hazards. The Soil Conservation Service helped to rehabilitate wells.

The Department of Defense aided in the evacuation of persons, and

provided spray crews and air transport for Public Health Service supplies and equipment.

PHS and NPA

The National Production Authority made critical materials available. A Public Health Service officer was named Kansas City representative, pro tem, of the Division of Water Utilities of the NPA.

When the third step, rehabilitation, was reached, the Public Health Service stepped aside for the Housing and Home Finance Administrator.

Although responsibility for civil-defense activities rests in State and local agencies, no community—no State—is able to muster all the supplies, equipment, and personnel, Mr. Pond said, that will be needed after a major attack with weapons of modern war used openly or covertly against the civilian population. Civil defense must plan for casualty services on an almost incomprehensible scale.

HEALTH SERVICE

CD Efforts Can Have Long-Range Benefits

"The local health officer's view of civil defense is really a worm's eye view," according to H. D. Chope, M.D., Dr. P. H., director of the San Mateo County public health and welfare department, speaking before the engineering section and conference of State sanitary engineers.

"Woe, worry, and work" have gone into the effort, yet Dr. Chope thinks it was wise to place the responsibility for civil defense in the hands of State and local health officers. He summed up the benefits and compensations accruing to the health officer from all the extra work under five heads:

Areas of Benefit

1. Working relations with other public officers have improved. Upon the local health officer rest the lives and safety of thousands of people.

2. Professional relationships have been solidified. Private physicians long have looked to the health department for advice in commun-

icable disease and tuberculosis control, vital statistics, and laboratory diagnosis. Under the pressure of civil defense, they look to health officers for aid and direction in related fields of medical practice.

3. Jurisdictional frictions have diminished.

4. Demands for a civil defense organization have shown that public health staffing is inadequate.

5. The health officer has discovered hidden potentialities in people. Nurses, engineers, laboratory and X-ray technicians no longer active in their fields or else employed outside the county, public health officers living in the county, and voluntary agencies have offered their services and been willing to subjugate their identities in an over-all organization.

Community Organization Value

Dr. Chope summed up: "If the time should ever come when our Nation is not threatened by the danger of war-caused disaster, it would be nothing short of criminal to allow to lapse all that we have accomplished to date in this particular field of community organization. The advantages which I have listed can apply to a peacetime disaster program just as well as they apply to the organization for a war-caused disaster. Although I do not advocate making disaster planning a seventh point in the standard public health program, I do feel that it should be an obligation of every local health officer to keep current at least a paper plan for disaster and bring into his planning and organizing as many community facilities and agencies as possible. The fact that we were so poorly prepared and it has taken us so long to work out our present plans, I feel is an unhappy commentary on the foresight of local health officers throughout the Nation. We all hope that neither war-caused disasters nor peacetime disasters will overtake our communities but should this occur, local health administrators should be prepared to provide the essential community leadership to meet the situation."

California at Threshold of State-Wide Sanitation Plan

California is "at the threshold of the actual job of developing an adequate state-wide civil defense environmental sanitation program," Arve H. Dahl, chief of the sanitation section of the division of medical and health services, State Office of Civil Defense, told the session.

Preparations have included, Mr. Dahl said, agreement with other divisions of the civil defense organization on areas of concern; development of an operational manual for environmental sanitation procedures and policies; working with health department sanitation personnel on how to serve as the catalyst to make this program possible; and development of plans and material for training of auxiliary personnel.

Seven environmental sanitation areas to be considered by divisions of medical and health services in every civil defense organization were listed by Mr. Dahl: sanitation of emergency medical facilities, emergency water supplies, emergency sewage disposal, emergency food sanitation, emergency vector control, service to evacuation and welfare services, and industrial sanitation.

Mr. Dahl reported that in Los Angeles the city health department has produced television shows instructing families on how to take care of sanitation problems around the home. "The education of the public in sanitation procedures is one of our key objectives," he said.

CD Records Systems Cannot Be Improvised After Attack

"The totality of modern war requires civil defense, and civil defense requires reliable quantitative information which will reveal the status of the essential resources, the population and the environment—before, during, and after enemy-caused disaster," Henrietta Herbolzheimer, M. D., M. P. H., deputy director in charge of health services and special weapons defense of the Illinois Office of Civil Defense, maintained before the statistics section

and the American Association of Registration Executives.

Dr. Herbolzheimer said that record keeping and information services to meet the demands of a colossal emergency cannot be improvised after attack. The system must be set up in advance and be "extremely simple, flexible, and foolproof." She cited four needs: (1) forms for tallies of resources and a system to keep the inventory current during operations; (2) information on population distribution and composition to carry out vulnerability analysis, and to make casualty estimates; (3) a definition of a casualty; and (4) records to cope with the population problem after incident.

It is up to civil defense to plan for the kind of evaluation services which will procure operational intelligence at the time of a disaster and in the postdisaster period for rehabilitation, the Illinois official said.

3-Fold Task of Laboratories Requires Advance Planning

Laboratory services for purposes of civil-defense planning are those concerned with the role of the laboratory in (1) the detection of actual or potential disease-producing biological or chemical agents whether naturally occurring or disseminated by enemy action, (2) diagnostic and management procedures employed in clinical medicine, and (3) the investigation of causes of morbidity and death, Gustave J. Dammin, M. D., laboratory consultant to the Federal Civil Defense Administration and professor of pathology at Washington University School of Medicine reported to the engineering, epidemiology, health officers, and laboratory sections.

The responsibilities at State level resemble, in a general way, those at Federal rather than local level in that they are (1) advisory, (2) coordinative with reference to critical target areas, (3) concerned with provision of financial support, and (4) supportive in providing such services as definitive studies in microbiology and other diagnostic procedure, Dr. Dammin said.

The basic operating responsibility for civil defense is in the individual and his local government, Dr. Dammin said. Clinical and anatomic pathology services and public health laboratory services must continue in a similar but somewhat restricted form in the postattack phase, and the preattack training should be related mainly to monitoring procedures. The laboratory service unit should be active now in conducting an inventory of personnel, supplies, equipment, and facilities. All technicians, active or inactive, should be known to the laboratory service unit of the civil defense health service, he emphasized.

BIOLOGICAL WARFARE

Research, Epidemiology Support Local Action

The Federal Civil Defense Administration will furnish leadership and planning for defense against biological warfare, but an effective defense rests on State and local efforts, and requires the complete cooperation of health organizations and professions, a joint session of the engineering, epidemiology, health officers, and laboratory sections was told by Robert H. Fllnn, M. D., and Norvin C. Klefer, M. D., of the health and special weapons division of the Federal Civil Defense Administration. They warned that a determined and resourceful enemy could effectively employ biological warfare agents against humans, animals, and crops, either by sabotage or by overt attack.

Many Pathogenic Agents

Any of a wide variety of pathogenic agents could be employed against our people, they declared, and could be disseminated through air, food, or water in a number of different ways. They listed civil defense measures in five broad categories:

1. Detection. A wide variety of instruments are available for air sampling, but better methods are being sought. Initial recognition of unusual agents in air, water, or food

is a task for local laboratory technicians, who can also in many instances identify the agents. The FCDA hopes to provide the special training necessary for these tasks through existing Government facilities, such as the technical centers of the Public Health Service. Federal or federally sponsored laboratories, organized on a sectional basis, will provide more exact identification where needed.

Initial Diagnosis of Cases

2. Epidemic intelligence. In many cases, the first positive evidence of biological warfare attack is likely to be the diagnosis of actual cases of disease. Prompt diagnosis and immediate reporting of such diseases would be imperative. Existing epidemiological and reporting systems require expansion, strengthening, and integration into a nation-wide network, sponsored by the Public Health Service, Drs. Flinn and Kiefer said. For actual investigations, mobile teams of qualified epidemiologists, sanitary engineers, veterinarians, public health nurses, and other professional personnel should be organized.

3. Personal protection. Although it is not feasible to immunize the general public against all probable biological warfare agents, the civil defense agency, and the health agency in each target community should be prepared to conduct a rapid immunization program at any time it is advised to do so. In addition, methods and materials for treatment with biological preparations, antibiotics, or drugs should be ready for any emergency.

A well-informed public is necessary to check rumor and panic. The FCDA booklet, "What You Should Know About Biological Warfare," has been given wide distribution, and a print of the 16-mm. film based on the booklet has been provided to each state and regional civil defense director.

4. Collective protection. Air-conditioning systems of key buildings must be protected against sabotage, and air-raid shelters should be

equipped with adequate filters. The best defense against sabotage, in addition to internal security measures, is the expansion and maintenance of rigid safeguards for water and food supplies.

5. Decontamination. For ground, streets, or buildings, flushing with a fire hose or, in some instances, washing with hypochlorite, might be necessary to remove biological warfare agents. Indoors, the usual washing, airing, and sunning procedures should be followed.

Dr. Flinn and Dr. Kiefer warned that nonbiological attack, for example, by an atom bomb, might result in contamination of water supplies and destruction of sanitary equipment, thus inviting the spread of diseases usually present in the United States.

Funds made available to FCDA for biological warfare are very limited, the two officials noted. Plans call for intensive training of approximately 350 public health administrators, laboratory personnel, epidemiologists, sanitary engineers, and other specialized personnel, using the Public Health Service facilities already in existence for training and research purposes. The health and special weapons division is also planning to stockpile antibiotics and biologics needed for protection against biological warfare.

Sectional Research Program To Stimulate Microbiology

Plans for a sectional research program in microbiology to encourage original research in problems of infectious disease and to develop more definite collaboration between research centers and health agencies was announced to the joint session by Dorland J. Davis, M. D., of the National Microbiological Institute, Public Health Service.

Patterned after the influenza study program, the microbiology program will have 12 outstanding investigators in various parts of the country working with other scientists in their vicinity. Associated with each of them will be from 5 to 10 nearby participating laboratories located in universities, State health

departments, hospitals, or research institutions.

These laboratories have been selected to cover broad fields of interest in microbiology. In general, there are laboratories in each section which have specialized interest in virus, rickettsial, mycotic, exotic, bacterial, and veterinary diseases transmissible to man.

Research, Not Administration

Research grant funds will be available for the support of this research, Dr. Davis explained. The laboratories will not do routine diagnostic work, nor participate in public health administration.

Information from the participating laboratories will be made available to the State health officers through Public Health Service regional medical directors. The program will be coordinated in the National Microbiological Institute of the National Institutes of Health.

Investigations of the Communicable Disease Center and State health departments may be supported on request by such services as the laboratories of the sectional research program are willing and able to provide.

This program should bring beneficial results not only in better preparation for national defense but also in improved methods for normal public health activities and particularly in reciprocal collaboration between research centers and official health agencies, said Dr. Davis.

New PHS Epidemic Aid Plan Provides Training and Services

Because of the lack of trained epidemiologists even for peacetime needs, the Communicable Disease Center of the Public Health Service has organized an epidemic intelligence service, with the ultimate objective, as described by Alexander Langmuir, M. D., and Justin Andrews, Sc. D., of promoting a wider understanding and appreciation of epidemiological approaches to the problem of disease control.

In July 1951, a group of 21 medical officers began training in epi-

demiology, biostatistics, and public health administration as it relates to communicable disease control. Following this course, they were assigned to selected field training areas, either in State or local health departments or in Public Health Service field stations. All of the men will be available for epidemic aid services upon request.

As a result of this training, some of the officers may remain in full-time epidemiological or public health work, while the others returns to civilian academic or clinical practice, but in the event of war they could be returned to active duty with the Public Health Service, Drs. Langmuir and Andrews said.

Knowledge of Public Health Environmental Factors Poor

Our concern about biological warfare is really a recognition that our knowledge of environmental factors affecting the public health is deficient in many important respects, Leslie A. Chambers, Ph. D., research

director of the Public Health Service's Environmental Health Center, Cincinnati, told the joint session.

There is insufficient information available at present on the viability of airborne organisms when subjected to adverse environmental influences such as sunlight and dessication, he pointed out. As a consequence, "we cannot predict, even roughly, the dosages that might be delivered to a population exposed to a biological attack by the airborne method." There is similar lack of information, he said, with respect to the number of bacteria or viruses necessary to produce a disease reaction in a human host.

Dr. Chambers noted that diagnostic bacteriology, as now practiced, depends to a large extent on a knowledge of the source of the sample and the conditions with which it is associated. There is need for the compilation of a concise, systematic approach to the laboratory determination of potential biological warfare agents in whatever type of materials

that come into question, he said. He also declared that more rapid identification procedures can and must be devised.

Organized Animal Disease Control Basic BW Defense

Basically our defense against biological warfare on animals is an effective organization for communicable disease control, Frank A. Todd, D. V. M., consultant on veterinary services for the health and special weapons division of the FCDA, told the joint session. The Bureau of Animal Industry, cooperating with State veterinarians, provides the nucleus of such an organization, he said.

In the event of widespread outbreaks of animal diseases deliberately introduced, he said, the normal control measures, such as quarantine, disinfection, and destruction of exposed animals, might necessarily be modified or augmented, possibly by the use of vaccines or other biologics.

Food and Nutrition

EMERGENCIES

Morale, Panic Control C. D. Nutrition Purposes

Bread will earn its title, "staff of life," Robert S. Goodhart, M. D., scientific director of the National Vitamin Foundation, and Norman Jolliffe, M. D., director of nutrition, New York City Department of Health, told the food and nutrition section.

Speaking on emergency feeding plans of New York City in case of a catastrophe, Drs. Goodhart and Jolliffe said that the primary purpose of a program is not nutrition but the maintenance of morale and the avoidance of panic. It must be designed to take care of special groups: (1) children, expectant and nursing mothers; (2) sick and injured; and (3) essential workers.

Nutritional requirements for periods of 1 week or less are both quan-

titatively and qualitatively less than allowances for longer periods. These doctors emphasized that during the first 48 to 72 hours after a bombing the only essential nutritional requirement for the major part of the population, to maintain life, is water. Many of the essential nutrients are stored in the body to a considerable extent. Thiamine is the only micronutrient a deficiency of which has been shown to produce symptoms in man within less than a month.

If bread only is available, the doctors said, sufficient nutrients in an accepted form to sustain life and morale for a period up to a week can be supplied by 1½ pounds of bread daily. However, menus are planned to consist of 1 pound of bread plus about 400 calories from other safe, locally available foods. It is expected, they said, that these minimum nutritional allowances will be exceeded in most instances.

Essential workers should be given a meal every 4 hours while working. The allowances for them per meal have been set as follows:

Energy	-----cal--	1,400
Protein	-----gm--	25
Thiamine	-----mg--	0.875
Water	-----qt daily--	4

When the nutritional requirements are modified by disease, injury, or burns, the maintenance of an optimal balance of electrolytes and fluids during the first 24 hours often determine survival, these doctors said.

Burns and Radiation

In the practical nutritional care of patients with severe thermal injuries, prophylaxis is preferable to and easier than therapy, Stanley M. Levenson, M. D., of the Army medical nutrition laboratory at Chicago and the Medical College of Virginia, Richmond, told the food and nutrition section in a paper prepared

with Elizabeth A. Lounds, M. A., and Mattie M. Robinson, B. A., of the dietary department of the Medical College of Virginia.

Complete Metabolic Mixture

Dr. Levenson stated that the food provided to burned victims must be a complete metabolic mixture containing adequate amounts of protein, carbohydrates, fat, minerals, water, and necessary food substances. If possible, the nutritional demands should be met by oral feeding. If not, gastric, jejunal, and parenteral feedings, singly or in combination, must be carried out, he said.

The optimum quantities and proportions of the various foodstuffs have not yet been established, and investigators are not agreed as to how early high intakes should follow injuries. But, Dr. Levenson said, children receiving from the start an intake one and one-half times that recommended by the National Research Council as optimal for normal individuals remain in excellent nutritional status following severe burns.

Male adults (previously well) receiving from the start an intake of $1\frac{1}{2}$ grams of protein and 45 calories per kilogram of body weight show nutritional depletion if the burn is severe—but less than if this intake is not begun very early. The nutritional requirements of nonpregnant women suffering from severe burns are lower than those of males with similar injuries.

Dr. Levenson and his colleagues recognized that, although supplying adequate food to patients is simple and easy in theory, practically it is often difficult. The ill patient often has a poor appetite and will not eat. Furthermore, shortage of kitchen and ward help and adequate nursing staff makes the control of diets difficult. Often the most important dietary items are not consumed. Under these conditions, he said, it is well to place the major emphasis on high-protein, high-calorie, and high-vitamin liquid diets. In the case of mass casualties from radiation injury, the liquid diet is apt to prove the more practical method.

Dr. Levenson emphasized that there is not enough information at hand to outline with certainty the nutritional care of patients with radiation injury. Data available suggest that individuals in good nutritional status at the time of injury resist radiation injury better than those in poor nutritional states; that morbidity and mortality are less in individuals whose nutrition is maintained at high levels after injury.

In cases of combined thermal and radiation injury, Dr. Levenson said, it probably will not be possible to feed the patient orally to the same extent as patients with burns only. The effects of antibiotics on nutrition have yet to be determined; the place of blood transfusions is not established; nor is the role of sulfhydryl compounds and various hormones.

FOOD PROCESSING

Antibiotics, Radiation Possibilities in Canning

Procedures that may revolutionize the processing of canned foods—such as the use of antibiotics and various types and sources of radiation—are on the horizon, Charles F. Townsend of the western branch laboratory of the National Canners Association and the University of California laboratory for research in the canning industries predicted before the food and nutrition section.

The rapid changes in methods and scientific knowledge demand constant readjustment on the part of all those concerned with scientific canning, Mr. Townsend said. Education in the principles of processing procedures is as important for the public health worker as for the canning operative.

High Speed Evaporation

The direct and indirect effect on the general public health of recent food processing developments which have made possible rapid evaporation at high speed—not at higher temperatures, but at extremely low temperatures—were discussed by

George D. Armerding, of the Mojonier Brothers Company.

Mr. Armerding said, "Not all of the bad factors encountered by reason of low temperature evaporation can be chargeable to the manufacturer or producer." He went on to show that the dilution or reconstitution of frozen orange juice concentrate is out of the control of the producer.

Health Laws Needed

There are some disadvantages, Mr. Armerding admitted, but he said that the very fact that we recognize them will bring about a way to eliminate them. These low temperatures are optimum for the development of bacteria, mold, and yeast growth or fermentation. It therefore becomes highly important so to construct the equipment that the product will be processed rapidly, continuously, and without the possibility of "pocketing." There is a temptation on the part of the operator to prolong the operating time without shutting down the machinery for cleaning at safe intervals. Health laws must be written to control such practices, Mr. Armerding said.

GENERAL DEVELOPMENTS

Enriched Rice Reduced Beriberi in Bataan 90%

Spectacular results in reduction of mortality from beriberi during a year of the rice-enrichment project in Bataan were reported to the food and nutrition section by Elena S. Quiogue, B. S. E., of the Institute of Nutrition, Department of Health of the Philippines.

For the last full year before the enrichment program (July 1, 1947 to June 30, 1948) there were 263.57 deaths per 100,000 from beriberi; for the first corresponding period during which the enrichment was in force (July 1, 1949 to June 30, 1950) the rate was 28.17 per 100,000.

During the first full year of rice enrichment, there was a decline of 67.3 percent in beriberi deaths in the experimental zone and an increase of 2.4 percent in the control

zone, as compared to the year before the enrichment program began. In the experimental area, she said, enriched rice had apparently saved the lives of 111 people in 1 year.

The Philippine Government is going ahead with plans to extend the benefits of rice enrichment to more of its people, she said. By the end of this year it is expected that 1,800,000 people, or approximately 10 percent of the entire population, will be reached. Because of the beriberi death toll of 4,400 persons per year "health authorities are greatly concerned about legislation providing for compulsory enrichment of all white rice in the country," Miss Quiogue reported.

Animal Nutrition

Discovery of insulin and use of cortisone and ACTH are outstanding examples of the rapid advance in the prevention and treatment of metabolic disturbances resulting from modern methods of animal feeding with purified diets, Agnes Faye Morgan, Ph.D., chairman of the department of home economics, University of California at Berkeley, told the conference of public health veterinarians. Similar imminent achievements are clarification of the etiology of high blood pressure, arteriosclerosis, and, possibly, cancer.

Animal feeding experiments carried on in the home economics laboratory of the University of California on fresh, evaporated, and dried milk, casein, lactalbumin, eggs, beef, peanut meal, wheat gluten, and other cereal proteins demonstrated differences in protein values of foods. At no level of feeding, Dr. Morgan said, did peanut meal or wheat gluten produce normal growth in young dogs, and when good proteins like those of milk, beef, and eggs were overheated, similar failures occurred.

Another experiment, in which vitamin E was fed at various levels to turkeys from 2 to 35 days before slaughter, showed that enough of the vitamin could be retained in the turkey tissues to act as antioxidant and prevent rancidity in frozen storage. Similar studies (done elsewhere) with pork were not successful, perhaps because of the lower retaining capacity of the pig tissues, Dr. Morgan felt. Experiments with rats and rabbits resulted positively as with the turkeys.

Diets poor in quality and quantity of protein, Dr. Morgan said, cause a depletion of liver protein and, consequently, of plasma proteins. Hence, "weight reduction by pregnant women should be cautiously directed so as to avoid any prema-

ture or unfavorable depression of liver tissue."

Nutrition Education

Growth of body, mind, and conscience is the goal toward which nutrition education is directed, Jennie I. Rountree, director, School of Home Economics, University of Washington, reported to a joint session of the dental health, health officers, and school health sections.

Nutritional knowledge can be used to improve family, community, and world conditions, she said, and one of the principal problems is to make the people realize the importance of food for efficiency, sane adjustment, long life, and happiness. Teachers have a splendid opportunity in the classrooms to influence their pupils, through friendly and interesting discussions of nutrition and its effect upon the individual.

Miss Rountree pointed out that the nutrition student "will see that undernourished bodies are tied up with pessimistic, self-centered, prejudiced, cynical minds; that hungry people cannot be interested in abstract ideals like democracy . . . Nutrition well taught will make people glory in America, its agriculture, its industries, its education, its research, its pure food, its public health mindedness and its possibilities for humanitarianism."

The Health of Mother and Child

RE-EVALUATION

MCH Needs Over-all View, New Study Criteria

"Emphasis on a holistic approach to the study of intra-uterine death and congenital defect is essential if the multiple causes which operate in human society are to be clarified and controlled," Theodore H. Ingalls, M. D., of the Harvard University School of Public Health, told the sections on food and nutrition, maternal and child health, and public health nursing.

Two centuries of observation and

scientific study indicate that acquired malformations are, for the most part, preventable, he pointed out, and said, "As yet, however, there is insufficient information upon which to base an effective program for the control of prenatal disease except that involving specific maternal infections.

"The mass problem is not a simple matter of cleft palates, or anencephalic fetuses, or maternal illnesses, but is concerned with maternal and fetal health as a holistic, biological system," Dr. Ingalls stated. Epidemiologically, the manifestations of prenatal disease are

revealed not as a collection of unrelated clinical entities, but as related series of time-specific arrests of development.

He said: "If anencephalus has epidemiological associations with spina bifida, and hydrocephalus; if mongolism cannot be studied satisfactorily as an entity unrelated to cleft palate, dental, and cardiac defects; if diabetes, erythroblastosis, and eclampsia have interrelation through hydramnios; if the problem of cerebral palsy of the brain, retrolental fibroplasia of the eye, and hyaline membrane of the lung overlap—then we are not coming to grips

with the totality of factors at work when each one of the problems is explored as though the others did not exist or had no reciprocal bearing on the one under scrutiny. This is not to plead against directed and limited efforts," Dr. Ingalls concluded, "but for the eventual synthesis of these efforts in the study of pregnant populations—a kind of Manhattan Project for mankind."

New York City Guide Lines

New criteria for maternity and newborn care programs to aid in evaluation of their present status and for the guidance of administrators and clinicians in program planning were called for by Helen M. Wallace, M. D., Edwin M. Gold, M. D., Margaret A. Losty, R. N., and Herbert Rich of the maternity and newborn division of the New York City Department of Health.

They reported on more than 7 years of experience in New York City. The study included records of births, deaths, and fetal deaths, surveys of hospital maternity and newborn services and reports to the health department.

Criteria developed from data reported to the health department have been used for studies of antepartum care, policies of hospital consultation services, hospital experiences of obstetric patients, and infant feeding. They also utilized the referral of antepartum patients with incipient serious medical or obstetric complications to the community public health nursing agencies for follow-up at home as a hospital criterion.

Maryland Maternal Program

An important gap in maternal care for low-income groups has been filled through a joint effort of the private physician and the Maryland State Department of Health, reported John Whitridge, Jr., M. D., and Edward Davens, M. D., of the department's division of maternal and child health.

They described the 23-year-old Maryland public health maternity

program, and interpreted statistical studies for a 6-year period (1945-50) covering 11,052 pregnant women.

Clinic centers in Maryland, the

study revealed, now serve approximately one and a third million of the State's rural population. In collaboration with a large teaching

The potential case-finding merits of lead I as compared to 12 leads of the electrocardiograph as a method for detection of heart disease was demonstrated by the National Heart Institute, Public Health Service, in an exhibit during the seventy-ninth annual meeting of the American Public Health Association in San Francisco.

The demonstration-exhibit was based on a study being conducted by the heart disease epidemiology study in Framingham, Massachusetts, where a group of 2,000 volunteers has been examined by this method. This study shows that inspection of lead I electrocardiograms permits detection of essentially the same

amount of heart disease as the 12-lead ECG. Further studies are being made on the practical application of this method, which is a simplified procedure consisting of a lead I conductor grasped in each hand or attached to the base of each index finger.

Over 700 ECG tracings were made in San Francisco as part of the Public Health Services exhibit-demonstration. Interpretations were sent to the participant's own physician, if he so desired. In the photograph, Dr. T. R. Dawber, in charge of the Framingham study, watches as R. E. Changon, technician at the Public Health Service Hospital in San Francisco, makes a tracing.

Cummings, M. D., of Emory University, the Veterans Administration Hospital, and the Tuberculosis Research Laboratory at Chamblee, Ga.

The investigators used lungs, livers, and spleens, because these organs represent a range of susceptibility to the invading organism, and employed rats, rabbits, and guinea pigs as test animals because of their resistance ranges. Amino nitrogen, total nitrogen, and the beta-hydroxy amino acid fraction were studied after normal values were determined.

Q Fever Studies

Antibodies to *Coxiella burnetii* were no more frequently encountered in syphilitic serums than in non-syphilitic serums, although false-positive complement fixation for syphilis was observed in 32 (7.5 percent) of 427 ill individuals in whom antibodies to *Coxiella burnetii* were present, the laboratory section heard from Edwin E. Lennette, M. D., W. H. Clark, M. D., and Florence Jensen, A. B., of the California State Department of Public Health.

Discussing the interrelationships of the serologic tests for brucellosis, syphilis, and Q fever, they reported that definitive diagnosis of Q fever had been made in all but 2 of the 32 patients in whom false-positive tests for syphilis were observed. In the case of brucellosis and Q fever, difficulties in specific diagnosis due to anamnestic or nonspecific reactions were rarely encountered.

Shigella sonnei Phase I

Shigella sonnei is of clinical importance only when it occurs in phase I, according to experimental indications reported by Sara E. Brenham, M. D., principal bacteriologist of the biologics control laboratory of the National Microbiological Institute.

Cultures from 20 carrier strains yielded at least 80 percent of phase II colonies, she told the laboratory section. For 55 strains from clinical cases, the yield was more than 80 percent of phase I colonies and 25 cultures yielded 100 percent phase I colonies.

APHA Conference Report to be Continued
in February Issue.

Head Nurse Activities In a General Hospital

This study came about as a result of a request to the Division of Nursing Resources, Public Health Service, from the Massachusetts General Hospital for "an analysis of the head nurse functions to see what can be done to relieve the head nurse either by reallocation of duties or by adding personnel to the ward staff to reduce the demands made upon her."

The study deals with the activities of five head nurse units for 5 days. Its aim is to determine what the activities of the head nurse are, how the nurse's time is distributed among her responsibilities, how much is devoted to non-head-nurse duties, whether any of these duties could be performed by other staff members, and how much additional time would be needed by each other category of personnel to perform them.

Environment and Health

This is the first book in the Public Health Service's 154-year history dealing comprehensively with environmental health, based on the modern concept of health as not simply freedom from suffering but the positive enjoyment of life in wholesome surroundings. The volume is subtitled: "Problems of environmental health in the United States and the Public Health Service programs which aid States and communities in their efforts to solve such problems."

The areas covered are: control of water and air pollution, food and milk sanitation, pest control, health and safety at home, refuse control, school and rural environments, sanitation of interstate public transportation, industrial health, radiological health, administrative problems, and research.

Environment and Health. (Public Health Service Publication No. 84.) 1951, 152 pages. Illustrations. From the Superintendent of Documents, Government Printing Office, Washington 25, D. C., 75 cents.

Industrial Health and Medical Programs

To facilitate the work of agencies and individuals whose concern is the development, administration, and improvement of health and medical programs for industrial workers, the Division of Industrial Hygiene has made this compilation from 260 books and publications of material on industrial health and medical programs.

The text, which consists entirely of direct quotations, provides background information about industry, the working population, the health of the worker, and the historical developments in the field of industrial health. It describes plant health and medical services and health and medical programs for industrial workers. Considerable data have been taken from several nation-wide surveys of general interest. Statistical data are used wherever available. The book contains no information on the clinical aspects of occupational medicine or the technical aspects of industrial hygiene engineering and chemistry.

Aging: Implications for Public Health

By CLARK TIBBITTS, B. S.

Population and aging in American life are emerging as a specific responsibility and opportunity for public health—responsibility, because public health shares the credit for extending life and creating the conditions which now command attention; opportunity, because of the tremendous significance that healthy, useful, and satisfying later years will have for our individual, family, and community life.

Later life, with its problems of adjustment, health, and security, faces more people in this country than it ever has before. Increasing longevity has come about almost entirely as a result of improvement in the environment of infants, children, and young adults—improvements based on biological research and scientific inventions translated into widespread public health and medical practices. At least 50 percent of all of today's children will live into the period which a generation or so ago was regarded as very old age. Older people have increased both numerically and proportionately since the turn of the century. The new problems, however, grow primarily out of changes in our ways of living.

In agricultural economies, older people generally find useful occupations and are active participants in family and community groups.

Mr. Tibbitts, a sociologist, from 1938 to 1949 was director of the Institute for Human Adjustment at the University of Michigan. He was director of the National Conference on Aging and vice president of the Second International Gerontological Congress and is currently chairman of the Committee on Aging and Geriatrics of the Federal Security Agency.

Industrialization and urban living, themselves made possible in part by public health engineering and sanitation, introduced many changes.

In this country, industry and commerce grew up in an environment of young people and developed a preference for younger workers. Use of machines and power increased the output per worker faster than the economy could absorb it. When a plethora of urban workers appeared and the economic situation demanded certain adjustments, the older people were retired and could find few outlets for their energies, as they might in most rural economies.

Furthermore, family life has undergone significant changes as a result of urban living. There are few common activities in the family to interest three generations, as there were in an earlier day. Thus the family has become the two-generation, conjugal group living in dwellings both spatially and socially inadequate for three generations. On the whole, grandparents are not regarded as essential to the young family of today. This, together with retirement from work, has helped to carry along the notion of uselessness in the older years. By and large, older people today are a bewildered group, eager to retain useful roles in the community but often made psychologically, financially, and medically dependent by a society which is only beginning to discover the true nature of aging and to recognize the great resources that reside in its older citizens.

Many individuals and groups are now studying aging and its meaning for individuals, families, communities, and for society as a whole. In the past 18 months, professional workers in many fields have met in a National

Changing Age Distribution in the United States

—Data from National Resources Planning Board: Human Conservation; the U. S. Government Printing Office, and U. S. Bureau of the Census: Current P-25, No. 39, May 5, 1950. Chart from Shock, N. W.: Trends in Gerontology Press, 1951.

people have both a need for creative and recreational activities and the opportunity to develop these skills through increased leisure. Furthermore, older people testify daily to the great satisfaction they find in having inner resources to draw upon when other responsibilities have waned. Recreation, handicrafts, and voluntary services offer the multiple advantages of providing activity, opportunity for social contacts and for making new friends, and for exercise which might otherwise be neglected.

The health educator and the public health nurse particularly can call the attention of older people and their families to the satisfactions inherent in working with their own hands and heads. Homebound older persons in institutions and in their own homes represent a particularly challenging group.

Recreation groups and clubs are becoming quite popular among older people. It has been suggested that these groups may offer an avenue for health guidance and counseling. In addition to these specific responsibilities, the public health profession clearly belongs in the community planning groups working out adaptations to the aging population.

Most older persons wish to live

in hom
ity to

By all means they wish to avoid segregation in colonies or in congregate facilities except where absolutely necessary. Yet, older people do require housing especially to fit their financial, social, and physical needs. Public health engineers have a part to play in these adaptations in housing.

Living Arrang

In Great the United States people will when frail available. tal care health n provision or assistance ing. Th individual number cilities

the housing needs of older persons are residence clubs, boardinghouses run by and for older people, and foster homes. Another arrangement is the construction of groups of single dwellings around a dormitory-type facility equipped with infirmary, central dining hall, community center, and workshops. Since these dwellings would be located inside the city, the residents would be assured necessary services and still be able to maintain contact with the whole community.

Public health is obviously involved in living arrangements for older people. It can participate by conducting research into housing requirements and by evaluating various types of living arrangements; by providing some of the supporting services; and by working with other community agencies toward integrated planning.

Health Promotion

To remain full-fledged, participating members of the community, older people must have the best possible physical and mental health. Health education and early detection of disease can postpone a good deal of disability, deterioration, and loss of physical and mental capacity. We who are aging need information about physical changes and how to live with them and about the availability of health services. We need guidance in such areas as diet, rest, exercise, and physical status. In order to maintain good mental health, many older people need individual or group counseling to adjust to such crises as loss of relatives or friends, retirement and reduced income, and the onset of chronic conditions. Public health workers can contribute greatly in this area by working with adult educators, employers, and other individuals and community groups.

Devices and facilities for the detection of incipient conditions, for assessment of health status, and for health counseling have been recommended in all of the major aging conferences. Further experimentation as well as demonstration projects of various kinds are urgently needed.

Despite improvements in health status that may be expected to come, the demands for medical care and rehabilitation seem destined to

increase in the future. It has been estimated that, within another generation, increases in the population coupled with the changing age distribution will double or triple the number of cases requiring treatment. How this need is met is important for the individual as well as for our entire economy. Clearly it is within the province of public health.

Medical Care and Rehabilitation

The immediate challenge is to devise or expand services that will restore as many as possible sick or disabled older persons to self-care, independence, and usefulness. A few institutions and rehabilitation and community centers are showing that this can be accomplished.

Home care programs, rehabilitation centers in local hospitals, more effective use of State rehabilitation services, and the employment of specialists who visit nursing homes and homebound individuals in order to teach them new skills and activities are all new developments with a great deal of promise. For those who require long-term services, new facilities must be developed instead of relying on the acute hospital or the county infirmary. Connecticut, for example, is moving forward in developing a state-wide system of chronic disease hospitals, rehabilitation centers, and long-stay annexes, integrated with community hospitals, nursing homes, and placement facilities for foster homes. Full recognition is given to the dynamic nature of sickness and to changing financial and social circumstances, which, taken together, call for varied and flexible facilities. In such a manner, therapy can be progressive and patients can be moved about as their condition warrants.

Nursing and old-age homes are examining their locations, facilities, and programs in recognition of the modern concept of older people as alert, participating, contributing persons. New standards are being developed for congregate living facilities, in compliance with Public Law No. 734, 81st Congress. Nursing-home operators have organized in nearly half the States. They are eager to work with public health and welfare agencies in designing facilities and in providing services that are safe, stimulating to the individual, comfortable, and

reasonable in price. Administrators of various institutional facilities are beginning to see the merits of maintaining close relationships with acute hospitals, community nursing and information services, occupational therapy programs, and educational institutions.

Certainly this is an important area for public health planning. Numerous States, counties, and cities are waiting for the health department or some other community agency to take initiative in this field. Because so much of the community planning, facilities, and services revolve around health status and medical care, and because it touches the professional interests of a variety of health workers, it seems logical to expect the health department to play an increasingly important part in conserving the health and welfare of older people.

An International Concern

Much of the material for this article has been drawn from the papers and discussions of the Second International Gerontological Congress, held in September 1951. This congress demonstrated that not only are the problems of aging world-wide but that many countries have already taken aggressive steps to meet them. Some of the outstanding progress in providing suitable living arrangements for older people and in organizing modern institutional and rehabilitative services has been made by countries which have had to face the problems earlier than we in the United States. Certainly there is much that we can learn from the experiences and programs of other countries.

The congress, like the National Conference on Aging before it, was organized on the broadest possible front. Its four sections considered such fields as biological and medical research, sociology, psychology, education, religion, economics, welfare, housing, and health services. This suggests the variety of factors which must be considered in meeting the needs of older people and the interrelationships which must always be kept in mind. The question of health ran like a thread through the discussions in all the sections; conversely, health workers need to be aware of the many related problems of the aging which affect physical and mental status and are affected by it.

Objectives and Action

The congress had three major objectives: (1) to provide an international forum for the exchange of ideas, information, and recent research, (2) to promote additional research in aging and to identify the areas in which research is most needed, and (3) to identify and stimulate action programs in the field of aging, using the knowledge now in our possession. Particularly in the section on health maintenance and services was the feeling strong that the people seem to be ready for action programs and that existing knowledge can be put to work in an effective manner. The participants agreed that health and welfare workers must prepare to give increasing attention to the continuing needs of older people.

Of significance to public health workers was the preventive approach which underlay much of the discussion. The emphasis was on retaining function and on conserving and utilizing capacity as long as possible. It was in this framework that the participants looked at accident prevention, housing and living arrangements, and even medical and rehabilitative services.

Blueprint Needed

The congress did not present a blueprint of public health services or community action for an aging population. The field is new; experimentation and continuing research were urged at this conference and by every other group that has studied the problem. Many of the research needs fall directly within the province of public health, such as studies to develop measurements of capacity, aptitude, and performance, and community surveys of needs and resources.

It is clear, too, that the public health profession is involved in human aging and its meaning in contemporary life, not by itself but in concert with many other professions and groups. Public health workers—all of us—will do well to remember that we are all aging right now, and that what we do for and with older people today we shall be doing for ourselves tomorrow and for those who come after us.

The Second International Gerontological Congress

By arrangement with Dr. E. V. Cowdry, president of the Second International Gerontological Congress, 24 papers read at the meeting in St. Louis in September are presented here in brief. These papers were selected for their particular application to the field of public health and are not necessarily representative of the entire congress. Selection was determined to some extent by the availability of the papers. In abstracting, the original language of the author has been retained as much as possible, and his approval has been obtained for the use of his work.

The Health Insurance Plan Of Greater New York With Its Older Enrollees

By GEORGE BAEHR, M. D.,
President and Medical Director,
and NEVA R. DEARDORFF, Ph. D.,
Director of the Division of Research and
Statistics, Health Insurance
Plan of Greater New York

The Health Insurance Plan of Greater New York is a voluntary, nonprofit corporation operating under the insurance laws of the State of New York. Every kind of medical and surgical service is available to its 282,000 subscribers. Because of the absence of age limits, a fairly large number of old people are insured under the plan. On May 31, 1951, persons of 50 or over constituted 18 percent of the total enrollment; about 15,000 members were over 60, and almost 6,000 were over 65 years of age.

Analysis of the utilization of physicians' services in 1948 and 1949 reveals that the rates for all HIP enrollees were identical in both years and that there was comparatively little difference in the utilization rates for older and younger persons. About the same proportion of services was given to people both under and over 50 years in physicians' offices or in group medical centers.

Proportionately, only half as many home calls were made to older persons as to persons under 50 years. On the other hand, the proportion of physicians' visits to older persons in hospitals was about 46 percent higher than such visits to younger persons.

The 929 persons of 70 and over, both men and women, had an average of 3.4 office visits, less than one-half a home visit, and less than three-quarters of a hospital visit in 1949. Thus, a wide margin remains for people of this age to increase their rate of utilization without creating any serious pressure on a plan like HIP.

Older persons had a slightly larger fraction of their care given by the general physician than was the case with persons under 50. HIP records show that older persons require comparatively more service from internists, general surgeons, and urologists, as would be anticipated. Older persons in the HIP population have also required more surgery, with the demand from males exceeding that of females.

Unless, in its enrollment process, it has attracted an excess of unhealthy people under the age of 50 and an excess of healthy people over that age—which seems most unlikely—the experience of the Health Insurance Plan of Greater New York demon-

strates that older persons are not excessive users of physicians' services. Enrolled in the proportions in which they occur in the general population, older people do not present problems of any magnitude or seriousness to a properly conducted plan of prepaid comprehensive medical care.

There is much to be learned about ways to improve medical care for the aging; a higher utilization rate among the aged may occur as more is learned about the possibilities of improving the health of older persons. There is no reason to believe, however, that the inclusion of the aged in a prepaid comprehensive medical care plan should materially affect the premium rates necessary for good medical care of families at various ages in life. As soon as geriatrics becomes a well-defined and generally recognized medical specialty, with sufficient representatives to undertake work in considerable volume, the HIP medical groups can integrate geriatric services in the same way as pediatric services are now incorporated in the groups' medical programs.

Involuntary Retirement and Morbidity and Mortality

By M. L. BARRON, Ph. D.,
Department of Sociology
and Anthropology, Cornell
University

Cornell University is engaged in a 7-year longitudinal nation-wide study to test the hypothesis that involuntary, unplanned retirement based on chronological age accelerates morbidity and mortality and aggravates symptoms of senility. Differentials on morbidity and mortality will be obtained for the following groups, among others:

1. Those continuing fully active vocationally after 65 versus those fully retired.
2. Those who retire abruptly at 65 versus those who gradually retire.
3. Those retiring involuntarily versus those who retire voluntarily.
4. Those retiring without plan versus those retiring on a planned basis.
5. Those remaining at work after 65 for economic reasons versus those continuing for other reasons.

Two pilot studies in an industrial plant in Ithaca, N. Y., and a community study in Elmira were undertaken to determine the variables in old age which may affect or be affected by retirement. These studies will be used as a starting point for a 1-year nation-wide survey of a representative group of 1,000 urban people, aged 60 and over, and for a series of follow-up, in-plant studies commencing with 64-year-old people who are gainfully employed. Long-range checks will be made on the physical and mental morbidity and mortality of the latter group, and detailed information will be obtained regarding health, activities, social roles, and other factors.

To determine attitudes toward retirement, more than 500 persons representing a cross section of the population were interviewed in Elmira. A majority indicated that the individual himself or a doctor, rather than an employer, the Government, or the union, should make

the decision as to when a person should retire.

Reactions to the statement, "Workers should be encouraged to retire at 65," elicited a response of 56 percent in accord. The youngest respondents held this belief to a far greater extent than middle-aged or older ones; apparently older respondents identify themselves with the problem of retiring at 65 much more than younger respondents. In response to another question, the answer to which might indicate bias on the part of the respondent, more than three-fourths felt that older people did not demand more consideration than they have a right to expect. The analysis by age indicated, contrary to expectation, that it was not the youngest group primarily who agreed to the statement. Rather, this prejudice among older people was registered to a greater extent by respondents who were apt to be influenced by stereotyped ideas of racial or ethnic group origin. Older respondents may be more prejudiced against persons of their own age, although other questions indicated that they were less arbitrary and more individualistic about decisions for retirement. This apparent inconsistency and others may be probed further in this extensive study to determine how the aged feel and to learn more about their behavior.

Something to Live For

By GEORGENE E. BOWEN,
Director, Philadelphia's Recreation for Older People

The Health and Welfare Council of Philadelphia asked the Philadelphia Recreation Association to undertake a program of establishment of recreation clubs to enrich the social life of many of the estimated 226,400 persons over 65 in its tri-county area. With the assistance of an advisory committee and a project director, together with 98 private and public organizations, a groundwork of understanding and cooperation was laid before actual promotion was begun.

The Recreation Association first obtained free space and facilities from settlement houses, city recreation centers, "Y's," churches, and homes for the aged. Sponsoring committees were formed to provide stability, financial backing, and volunteer help to the clubs.

Whenever possible, professional staff was used to work with older people, but mainly lay persons have acted as leaders and volunteers. At present 480 nonprofessionals are serving enthusiastically. Institutions, workshops, and conferences were held to train a total of 555 professional and nonprofessional workers.

The Program and Responses

Local sponsoring committees extended invitations to known older neighbors to participate in planned recreational activities. Although the problem of making contact with older persons is still baffling, the response of those who could be reached was immediate and enthusiastic. Today there are over 3,700 individuals gathering in 80 centers. They attend an average of 20 meetings a year.

At these "Golden Age Clubs," there is dancing, singing, playing games, painting, working at arts and crafts. Oldsters write and recite poetry, hold contests, take time for book reviews and current events, go on trips, and give dramatic programs.

The clubs are mostly neighborhood groups and vary in cultural and economic backgrounds. There are racial, cultural, and religious mixtures responsive to a single interest or to several. There are both employed and unemployed members of all economic strata. Class distinction does not exist—in a single club there is a blacksmith and a Ph. D. The age range is great, from 60 to 100 plus. In a span of 40 years two full generations may be represented.

The Community

Even though a leisure program has a powerful therapeutic force in the life of an older person, happy group association has a far-reaching beneficial effect on the community. The

older person is no longer a burden but an asset to his locality.

The club door swings both ways, admitting the community and at the same time leading the older people into community life to which they are quick to respond.

Illnesses and resistances which characterize the older and lonely individual often miraculously disappear. There has not been a single heart attack and only one minor illness at the club meetings. Finally, the negative attitudes of older individuals dissatisfied with their community change, and those of the community change too. Prejudice disappears, and tolerance of other faiths, races, economic and cultural levels takes its place.

Improving Health Care In Nursing Homes

By L. E. BURNEY, M. D.,
Health Commissioner, and
MARTHA O'MALLEY, M. D.,
Director, Division of Hospi-
tal and Institutional Ser-
vices, Indiana State Board
of Health

Institutional care of the aging is becoming increasingly important. Public health workers are interested in institutional care because of their responsibilities in problems of the aged, including chronic diseases, and because they are often required to assume functions in the inspection and approval of institutions.

Nursing homes, private and public, should provide adequate care and should maintain reasonable standards to safeguard the health and promote the welfare of their residents, particularly elderly people. One of the measures to assure standards is through the licensure and approval of institutions. There has been a definite trend in this country for States to enact laws requiring licensure of hospitals and nursing homes. This trend was stimulated by the enactment of the Federal Hospital Survey and Construction Act and by the recent amendments to the Social Security Act.

In Indiana, considerable study was given to the development of a sound

program for the licensing and approval of a number of institutions. The responsibilities of the State Board of Health are in the field of health and environmental sanitation. It works closely with the Department of Public Welfare, which administers the program of approval of county homes for assistance cases, and with other State agencies having similar responsibilities.

Most operators of institutions are sincere and well-intentioned, but they sometimes fail because of lack of awareness or understanding of the problems or because of inability to cope with the situation. Therefore, the program should be one of education and assistance, rather than of compulsion. Police methods should be resorted to only when all other methods fail. Standards and regulations should be in the form of basic principles rather than an outline of specific details. The application of principles allows for flexibility and encourages individual variation to meet particular situations.

There are certain common basic problems which have appeared in the work with county and nursing homes in Indiana. These are: (1) lack of a definite plan for care of chronic disease patients in different age groups; (2) lack of community understanding and support; (3) lack of a representative group of citizens to work with operators of homes on policies and programs for care; (4) need for administrators to understand program planning and the needs of chronic disease patients; (5) need for supervision of nursing care by qualified registered nurses; (6) need for well-balanced diet and meal planning for the aged and chronically ill patients; (7) almost complete absence of physiotherapy services; (8) the little effort made to keep the persons in county or nursing homes occupied; (9) the limited amount of medical care now provided, which is usually on the basis of individual need rather than on a definite plan of supervision and care; and (10) need to improve the physical structure to provide good environmental sanitation and to modernize utilities and service facilities.

A comprehensive evaluation of present health needs of older people and a plan based on their needs should be made. The plan should include an allocation of public and private nursing home beds based on realistic criteria of need and on the proposed over-all program. This plan should be developed before licensing agencies proceed with regulations, since requirements should be directed to the program of patient care the institution is expected to carry out. A model set of regulations and standards for public and private nursing homes should also be developed to serve as a guide to States and counties in working out their own requirements. Personnel specifications should be established to include experience, training, and personal qualifications of the staffs of nursing and county homes. Finally, special training programs should be inaugurated for the licensing of agency personnel.

Nutrition, Senescence, And Rejuvenescence

By A. J. CARLSON, Ph. D.,
and F. HOELZEL, Ph. D., De-
partment of Physiology,
University of Chicago

More than 35 years ago, the senior author found that a 5-day fast, undertaken to study hunger, produced highly beneficial physical and mental after-effects. Marked general improvement lasting at least 6 months was experienced by Hoelzel following a 26-day fast in 1913, and similar improvement was experienced in 1917 following a 15-day fast, despite the development of nutritional edema.

These experiences seemed to support the findings of Child in experiments with planaria—that starving had some rejuvenating effect (Senescence and Rejuvenescence, University of Chicago Press, 1915). Child regarded the rejuvenation of planaria by starvation to involve an

increase in the rate of metabolism. Studies on three dogs and seven men confirmed this view although one study on Hoelzel did not.

In 1928, it was found that mental performance of three subjects was increased above the prefasting level for some time after fasting.

Prolonged fasting evidently produces the most striking effects and after-effects within the shortest time. Hoelzel found that a general improvement following intermittent fasting seemed equal to that following less prolonged fasts. In 1940, however, he found that, with aging, the ability to do light work while fasting one or two days evidently decreased, and the ability to become nutritionally rehabilitated rapidly after short fasts also decreased.

In a study on rats it was found that fasting 1 day in 3 was about the optimum for prolonging the life span without significantly impairing growth. Life span of rats fed a concentrated or rich diet *ad libitum* was shortened and fertility impaired, and it was impossible to maintain a population of 50 rats after the third generation. Ten generations were obtained from the most fertile rats before reproduction failed completely, but this represented a total breeding span approximately no longer than the single life span of some of McCay's long-lived rats.

An impairment of reproduction can be considered as representing an impairment of the periodic rejuvenation which normally prevents a cumulative aging of the species. The observations of Rudzinska on *Tokophya infusionum* have shown that overeating can impair reproduction and shorten the life span of lower organisms, and the authors believe that their findings on rats apply also to man.

Fasting or prolonged food restriction, if not carried too far, can evidently produce conditions in which the organism can at least temporarily utilize larger amounts of food than can be utilized at the same age by a continuously fed organism. On a purely physical basis, nothing may be gained, as the decrease in energy production during food restriction may only be balanced by the increased energy production during

nutritional rehabilitation. However, improved mental functioning during nutritional rehabilitation may outweigh depressed functioning during food restriction.

It is possible that the striking beneficial after-effects of prolonged fasting may be due to a hypertrophy of the adrenals or that the nonessential tissues used up in starvation may include abnormal accumulations of some intermediary product of metabolism.

Illness Among Older People in Hagerstown

By A. CIOCCO, M. D.,
Graduate School of Public
Health, University of Pitts-
burgh, and P. LAWRENCE,
M. D., Division of Public
Health Methods, Public
Health Service

This paper is an analysis of data gathered in two house-to-house surveys, conducted 20 years apart, 1923 and 1943, in Hagerstown, Md. The analysis is concerned with the occurrence of chronic illness and death in the 20-year interval and with the relationships involved. The longitudinal type of study, i.e., a study based on repeated observations on the same group of persons over a period of time, is a valuable method of answering some of the important questions related to an aging population, particularly sickness and disability trends.

From findings in the National Health Survey and the Hagerstown survey of 1943, it is estimated that at age 65 about 40 percent of the population have some chronic disease or major impairment. Although this measure of prevalence is valuable, it does not measure change—the relationship of current health status to past exposure to disease. For this information, it is necessary to obtain data on incidence, which, for the chronic diseases, require the longitudinal approach; this permits us to observe the frequency of change in a group with known characteristics by fol-

lowing the same individual over a span of years.

Analysis of the data shows that of persons 40 to 50 years of age in 1923, less than 50 percent were alive and without chronic illness in 1943, and only slightly more than 20 percent of those who were 50 to 60 years old in 1923 were alive and well in 1943. Previous chronic illness has an unfavorable effect on future health status. A substantial proportion of the persons who are ill at 65 have had the same or another chronic illness for at least 20 years. This leads to the conclusion that, if disease is to be prevented in the man of 65, observations must be begun and action taken before he is 45.

Approximately 100 of every 1,000 persons who are well at age 45 will require, during the next 5 years, medical attention for the onset of a chronic disease or a major impairment. Some will require periodic medical treatment, but a few will need almost constant medical care of some kind until they die. Nearly 25 percent of those who are well at 60 will develop, within 5 years, a chronic ailment for which they will probably require medical care and, in many cases, care of a continuing nature.

Management of the Older Employee With Medical Problems

By RUFUS B. CRAIN, M. D.,
M. P. H., Medical Director,
Kodak Office and Camera
Works, Eastman Kodak Co.,
Rochester, N. Y.

The Eastman Kodak Company emphasizes the value of selective job placement and follow-up of workers with physical or mental disabilities. Job descriptions now include information concerning physical requirements and job environment, and the total information is made available to the medical department. Thus, it is possible to match physical capacities with work requirements. This system has disclosed a number of jobs not previously recognized as

suitable for the older or disabled worker.

The company's experience with accident and sickness rates reveals that age is a factor contributing significantly to the sickness-disability rate. Men 40 years of age and over lost nearly two and three-quarters times as many days per person as those under 40. Likewise, older women (40 and over) lost nearly one and three-quarters times as many days per person as younger women. However, age is not a problem as far as industrial injuries are concerned. On the basis of the number of lost-time injuries per 1,000 employees, the company has found that the rate of disabling injuries is roughly the same in all age groups.

The company's nutrition department carries on a general educational program for workers, as well as counseling for managers of cafeterias and service dining rooms and individual counseling with employees. Many older people referred because of such conditions as overweight or underweight, osteoarthritis, hypertension, etc., have been greatly benefited by proper diets.

As a result of a growing need for attention to personality disorders and problems of adjustment, a psychiatrist was added to the staff of the medical department on a part-time basis. The preventive aspects of the psychiatric program are stressed, consistent with the company's conviction that continuing education in the psychological and psychiatric approach to employee problems is necessary for all levels of management. Psychosomatic disturbances, particularly the anxiety type of neurosis, account for the majority of mental disorders found in industry. On the basis of the experience of the Eastman Kodak Company, age does not appear to have any striking effect on the type of personality disorder encountered.

Experience with employees having cardiovascular disease indicates that, with proper placement and follow-up, persons with various impairments may be satisfactorily employed.

Normal retirement, with eligibility for benefits commensurate with length of service, occurs at age 65.

However, most people may continue to work for Eastman Kodak as long as their health and ability to do their jobs permit. In the past few years, the company has instituted educational programs on preparation for retirement and on activities after retirement.

Clinical Problems In Gerontological Rehabilitation

By M. M. DASCO, M. D.,
Service of Physical Medicine and Rehabilitation,
New York City Department
of Hospitals (Goldwater
Memorial Hospital)

Rehabilitation of the aged aims to restore such persons to their fullest physical, mental, social, and economic usefulness. This definition clearly shows that the problem is more than medical and the aid of all ancillary specialists has to be enlisted to rehabilitate an aged person. In spite of the ever-growing scope of specialization, there are a great number of morbid conditions which always happen to be "outside the field" of any specialist. It is the duty of the rehabilitation specialist to handle these heretofore neglected conditions and bring about as full a restoration as the situation permits. Rehabilitation activities of elderly persons could be arbitrarily classified into three groups: (1) restoration of the obviously handicapped aged (such as those suffering from hemiplegia, arthritis, fractures, and neuromuscular diseases); (2) rehabilitation of those who are chronically ill but show no obvious signs of disability (patients with chronic cardiac and pulmonary diseases); and (3) restoration of the elderly person who has no manifestation of a specific disease but whose physical fitness is impaired.

With the basic principle in mind that a mere geriatric clinic is insufficient for the successful rehabili-

tation of an elderly patient, a gerontological guidance clinic is being planned, which will offer complete rehabilitation in terms of the definition given above.

Services Offered

The service will consist of three main sections, the first of which will offer complete medical and surgical services, including a complete physical rehabilitation service and nutritional consultation. The second will be the psychosocial service and will include a psychologist and social workers who will work in close cooperation with the psychiatrist and the rest of the members of the medical-surgical section. A domestic relations counselor will help to adjust the aged patient and his environment to each other and thereby eliminate the frequently observed friction between two or often three generations who are forced to live together. This section will also have housing and legal consultants to take care of the special problems arising in these fields.

The third will be the vocational and employment section, which will consist of a testing psychologist and a vocational and employment counselor. This section will advise on vocational training and retraining and will attempt to obtain employment for the successfully rehabilitated elderly patient.

Specialist Participation

Joint conferences with the participation of all medical and nonmedical specialists will make it possible to discuss all facets of the elderly patients' complex problems and will enable us to render a more efficient and realistic service to these people.

Such a service will not only be useful for the elderly sick of the community, but it will also provide essential counseling service for industry in helping them to establish a sounder retirement policy by replacing the archaic chronological system with one based on the worker's physical and mental status and his ability to perform.

The full text of this paper is scheduled to appear in a forthcoming issue of *Geriatrics*.

The Young Candidate for Coronary Heart Disease

By M. M. GERTLER, M. D.,
Department of Medicine,
Columbia University Col-
lege of Physicians and
Surgeons

Modern diagnostic methods have achieved a great deal in the diagnosis of the acute or subacute phase of coronary heart disease which terminates in myocardial infarction. The increasing death toll from coronary heart disease suggests that another form of approach to this problem be studied, namely, the prevention of coronary heart disease. In a recent study of 100 individuals who had experienced myocardial infarction prior to the age of 40, certain leads were uncovered which may help in recognizing the individual who is prone to coronary heart disease. One hundred and forty-six normal individuals of roughly the same physique, occupation, and ethnic origin were used as controls.

It is noteworthy that 42 men in the coronary heart disease group held managerial positions; 11 were professional individuals; 7 were semi-professional individuals; 4 were skilled workers; 30 were semiskilled workers; and 3 were unskilled workers.

On the basis of the study, certain phenotypic expressions were selected which are thought to represent the coronary heart disease profile pattern:

Hereditary History. Presence of coronary heart disease in any sibling or in either parent at an early age; history of metabolic diseases, arthritis; history of hereditary hyperuricemia and hypercholesterolemia.

Psychological History. Strong, goal-directed drives, usually with accomplishment; aggressive pattern not an outstanding feature; high athletic rating in contact sports; "less masculinity" in absolute values, as revealed by Terman-Miles test.

Anthropometry and Somatotype. Dominant mesomorphy; secondary endomorphy; decreased linear measurement (on the average the coro-

nary heart disease group was 2 inches shorter than the average height of the control group); increased horizontal measurements; no evidence of an abnormal increase in weight.

Biochemistry. Serum cholesterol elevated; serum uric acid elevated; serum lipid phosphorus slightly elevated; serum cholesterol/serum lipid phosphorus ratio increased; "CUP" index (cholesterol x uric acid/lipid phosphorus) increased; reduced intensity of saliva to low EMF (electromotive force) values; urinary 17-ketosteroid excretion, low normal; basal metabolic rate, low normal.

Clinical History. Usually no signs of heart disease prior to the coronary episode.

The question may be asked, "What may one do once preselection of the coronary-prone male is made?" It has been demonstrated that the relationship of the total cholesterol/lipid phosphorus ratio may reflect the stability of the cholesterol in the serum. The degree of intimal permeability to cholesterol may be a very important factor, for one could theoretically conceive of a condition whereby the coronary intima is impermeable to cholesterol or to its products. In view of this, preventive therapy would consist in re-establishing the total serum cholesterol/serum lipid phosphorus ratio and decreasing the permeability of the intima in the coronary arteries.

An Adequate Program Of Medical Care For Elderly People

By FRANZ GOLDMANN,
M. D., Associate Professor
of Medical Care, Harvard
University School of Public
Health

There is wide agreement about the need for a broad and well-balanced medical care program to meet the

requirements of the aged at the least cost compatible with adequate service. The problem common to civilized countries is the elimination of obsolete practices and policies, the improvement of services which have met the test of time, and the filling of gaps in accordance with current scientific knowledge and social philosophy.

Over-all Plan

Health needs of older people are numerous and complex and in some respects quite different from those of younger people. Generally, the amount and types of services needed, as well as their duration, substantially exceed those for younger groups. This situation arises from five factors: frequent occurrence; severity and long duration of physical and mental diseases; exacerbation of conditions originating earlier in life; serious course of some acute diseases in old age; psychological, social, and economic effect of illness in elderly people; and the social and economic setting within which elderly people live in many countries, particularly those in advanced stages of industrialization and urbanization.

Components

The program must include services of general physicians and specialists, dentists, pharmacists, social workers, professional and practical nurses, homemakers and housekeeping aides, and others possessing special skills. It must include a supply of prescribed drugs and appliances.

The essential physical facilities include diagnostic clinics, general and special hospitals designed to serve patients with long-term illnesses, nursing units or complete hospital sections in homes for the aged, and boarding or nursing homes under medical supervision. The diagnostic clinic is the heart of a forward-looking program.

As important as physical facilities for the sick is low-rent housing for the displaced elderly person, with provision for health supervision. Efforts should be made to maintain older people in their own homes. Organized housing projects should

replace huge institutions. Within large communities, housing projects should be equipped with small infirmaries and nursing service to provide care at home.

Organization of Payment

Orderly arrangements for financing programs are as important as their creation. Adequate physical facilities are expensive; the task of raising necessary capital may be beyond the power of any single group, voluntary agency, or political unit. Cooperation is the answer. General tax funds to supplement resources of voluntary organizations have been provided in some countries. Operating costs of a medical care program should be met through insurance, general tax funds, or a combination of both, with emphasis on self-help. An insurance system which will meet the needs of elderly persons must include medical care and disability and old-age benefits. To the extent that insurance funds are spent on health care and income maintenance, the need for public assistance declines.

To be effective and economical, a program for the elderly must assure comprehensiveness, continuity, and consistency of qualitatively adequate medical care through the stages of health, acute sickness, convalescence, and long-term illness. Health of the older person must be maintained, diseases associated with higher age prevented, and illness must be met through early diagnosis and prompt treatment. The program must cover service at the home, the offices of the doctor and the dentist, the diagnostic and treatment clinic, the hospital, and the institution designed for long-term care. Emphasis on institutional care, neglecting home and office care, is insufficient, unwise, and costly.

Specifications

Success of a health-service program for elderly people depends on progress in scientific medicine, especially gerontology; education of all people in the principles of healthful living; and the establishment and improvement of general programs of medical care for all age groups. Otherwise, such a program

will still be useful to the individual but extremely costly to the community.

Furthermore, income must be provided to enable elderly persons to maintain a decent standard of living. Also, such a program requires careful preparation, including arrangements for both systematic organization of service and for methodical payment. Execution by stages over several years may be necessary.

Organization of Service

There must be systematic organization of the services of professional and auxiliary personnel, of clinics, hospitals, and related facilities, and use of definite methods to compensate service personnel. Teamwork is essential because of the variety of health personnel and institutions involved. Differentiation of service and division of labor will go far to make the total program efficient and economical, reduce personnel shortages, and free expensive hospital beds. Organization and teamwork mean determining the functions to be performed by the various professions and use of a referral system among institutions.

Older People Live In Institutions

By BENJAMIN L. GROSSMAN, Executive Director, Drexel Home, Chicago

Institutional housing for older people includes the nursing home, both profit-making and nonprofit; homes for the aged, both public and private; county homes; infirmaries and hospitals for the infirm and chronically ill; and hospitals for the mentally ill. Older people enter institutions because they have a chronic illness, because of physical disability, because of personality difficulties, and because they are not wanted or needed in the family.

An institution for older people should be a therapeutic and rehabilitative agency. The approach should be individualized and founded upon a knowledge of human behavior and motivations. This implies a recognition and an acceptance of the fundamental principle that an older person's response to his problems will be like that of any adult.

When people who have grown older live in an institution, they have a right to good medical care, comfort, protection, privacy, freedom of speech and action, good nutritious food, proper social and recreational life, clean shelter, respect for their possessions, and the right to worship as they desire.

Licensing laws can help to improve and to insure the welfare of the people who live in institutions, and every State should have such laws. However, a law alone will not solve all the problems; it must be one element in a broad, constructive, community program. Laws need to be supplemented with methods for improving the low quality of care now provided in many institutions throughout the country.

A licensing law should be brief, simple, and clear-cut. In general, it should deal with broad objectives and leave detailed requirements for administrative rules and regulations.

Standards of good care and adequate services are vitally important. Administrators and operators of various institutions for the aged must be encouraged to provide the care which will result in maximum benefit for the people who live in the institutions. In its broadest sense, thus, the care of older people is a community problem.

Cost of Chronic Illness

By RAYMOND A. HILLIARD, Ph. B., LL. B., Executive Director, Welfare Council of New York City

Despite new medical discoveries—and there are certainly great advances in sight—there is much to be done in preventing chronic illness. It is now possible to say that at least

50 percent of chronic illness can be arrested if treated early enough. Moreover, rehabilitation can work new miracles.

In the social sciences, however, there is little progress to report. Society has relegated increasing numbers of old people to an economic and social scrap heap, with increasing evidence of discrimination against employment of older people. Handicaps of age have become as real as many of the physical handicaps, even though there is no connection between them.

Prevention Stressed

The most important approach in both medical and social spheres is for understanding and prevention rather than treatment. The social sciences should emulate the medical sciences in their conquest of chronic diseases, to insure equal success in attacking the social handicap of increased age.

Costs of chronic illness are both direct and indirect. The former are confined to medical and related services for nursing and hospital care. Indirect costs include employment loss not only by the chronic invalid but by those who must care for him. There are also social losses such as the "tyranny" imposed on the household in which the chronic invalid lives.

Perhaps as many as 25 million people have some chronic disease, and nearly 1 million deaths and 1 billion days of disability a year can be ascribed to such illnesses. It is estimated that between 1.25 and 1.5 percent of the total population have chronic illness of prolonged duration, requiring the help of others and progressing to a need for constant attention and special service.

Chronic illness is not a problem of the aged alone. It strikes devastatingly in the middle years.

Chronic invalidism is the greatest single factor, other than great economic depression, in forcing people onto public assistance rolls. In a typical Illinois county, almost one-fourth of all public assistance recipients were chronic invalids. Of the aged, well over one-third were chronic invalids. In addition to economic and physical care prob-

lems, chronic illness creates other problems: children or parents may have to give up employment in order to care for the sick; physical or emotional impairment of family members caring for the invalid may result in affecting others, in a "chain reaction."

Although the fields of geriatrics (diseases of the aged) and gerontology (the aging process) perhaps represent most-neglected areas of medical and social sciences, there is a present awareness of the great significance of the aging problem. Attitudes toward chronic invalidism need thorough revision. Too often there is a sense of shame, minimizing knowledge of the problem and hindering planning. Such an attitude is intensified by the fact that there are few adequate facilities outside the home, so that institutional care for an invalid is regarded as "unnatural" or "heartless."

This tragic situation can be corrected and these costs of chronic illnesses may be averted. Costs will double unless research, treatment, and rehabilitation are intensified.

Apart from functional disorders, old people deteriorate because they are not wanted—society has not planned for their utilization. Deterioration is hastened and promoted in the face of lonely years of unrelieved idleness. Community planning may provide some of the answers. In New York City, for instance, day centers provide a place where older people may gather. They rejoin society, become a part of things, and feel wanted. New York's Hodson Center has enrolled over 1,000 old people as members. Only one has entered a mental institution, although statistics indicate that on an average 40 would have been admitted. Here is prevention at little cost and one answer to the overcrowding of our mental institutions. Many more centers are needed, but government and private philanthropy cannot afford to provide them. The answer may be found in every neighborhood and in every community which has churches and synagogues. They have facilities and their members can raise funds and supply volunteer staffs. A precaution must be taken—churches

should initiate programs only with competent, trained, social work direction. And, as is done in child care, government can provide consultation services through welfare or health departments.

Exploring Housing Needs of the Aging

By BLEEKER MARQUETTE,
A. B., Executive Secretary,
the Public Health Federa-
tion, Cincinnati

The best available estimates indicate that probably about 95 percent of people over 65 years of age live in individual households, either alone or with others. Moreover, that is the way they seem to want to continue. The major problem in housing for older people is an adequate supply of acceptable housing units adapted to their ability to pay. There doesn't seem much likelihood of meeting the need effectively unless the over-all housing situation is improved.

The principal housing problems for older people occur among middle- and low-income groups. The solution for middle-income older people would seem to be the same as that for middle-income families generally, namely, more housing at moderate prices. For low-income families, where the situation is most serious and where housing is substandard and inadequate, some kind of subsidized housing is needed. If the aging are to benefit, a clarification of public housing policy is essential. More dwelling units must be provided for two-person and one-person families, and the single older person, as well as older couples, must be made eligible and welcome. This must be done, not at the expense of younger families, whose needs are, if anything, greater than those of the aging, but through the addition of more small units suited to older people.

Although many older people are able to make good adjustments in various types of living arrangements, most of them prefer to stay

in their own homes, even through mild illness. In order to enable them to do so, certain auxiliary aids should be made available to them. Among these are visiting housekeepers to help with housework, home medical and nursing care, and the services of social case workers. Some older people, particularly those who are single and are inclined to be lonely when living by themselves, want congregate living if they are not too greatly regimented. More such homes of the modern type geared to older people's wants and allowing a maximum amount of freedom of activity are in demand.

It is questionable whether housing units need to be specifically designed and reserved for older people. Some of the special housing needs of older people are special provisions for safety, doors wide enough for a wheel chair, elimination of stair climbing, heating and ventilating subject to control by the occupant, absence of excessive noise, and accessibility to transportation, stores, libraries, and other facilities. Rather than thinking in terms of promoting the development of housing units to be set aside for older people, a more practical approach might be to establish standards for features in housing that are desirable for older persons and also for other small households. Then a concerted effort might be made: (1) to persuade private builders to adhere to these principles in designing smaller units, and local housing authorities to incorporate them in their planning, and (2) to induce both groups to provide more of them.

Public and Private Community Planning For the Aged

By HENRY L. MCCARTHY,
Commissioner, New York
City Department of Welfare

The relationship between public and private welfare agencies in planning and executing programs for the aged requires re-examination in

the light of modern trends. Until recently, most assistance, especially institutional care, was provided by private agencies. Conditions of city and county homes and public mental institutions were for the most part bad.

Programs for the aged can no longer be thought of in terms of institutional care only. First, the question of employment of the older person has to be considered. Then, because of the rapid increase in urban population, housing for older people must be developed. Finally, there are more older people; better medical diagnosis and treatment have brought better health for more years of life than ever before.

Economic Status

The economic status of older people is fundamental to cooperation between public and private agencies. At best there are 20 percent of those 65 years of age or over who have sufficient income and health and are otherwise situated so that they have no need for welfare agencies. At the other extreme, purely economic, 22.4 percent of those 65 years of age and over must rely on public old age assistance. In New York City, those on public assistance rolls comprise 10.6 percent of all those 65 years of age and over. The present trend is toward a greater percentage of the aged finding support through public assistance and for greater liberalization of these programs.

Other services are available to those receiving assistance payments. In New York City, medical care, nursing, and housekeeping services in the home, convalescent home and institutional care, and social services are provided. The completeness of services available to recipients of public aid underlines the fact that those who are not quite eligible for assistance are much worse off than those who are on the program. Their needs are often great but they must look to private agencies.

Complete cooperation between public and private groups may reduce the public assistance lists. In the field of rehabilitation, public agencies should refer the handicapped to private organizations.

In addition to those who are re-

ceiving assistance or are entirely independent, perhaps another 25 percent of the older people are supported by their children. There are also 1.7 million beneficiaries under the Federal Old Age and Survivors' Insurance program. Other programs, such as the Railroad Retirement Plan and, of great significance, private pension plans, also provide support. We may be approaching a solution of economic problems of the aged, but money is not all that is involved.

Social Status

The idleness and isolation to which older people are often consigned bring many to the brink of despair. Mental and nervous breakdowns and possible commitments to mental institutions result. In New York, day care centers for the aged, sponsored by private agencies and the department of welfare, provide an opportunity for older people to develop a satisfactory social life of their own. They require less medical care and lead otherwise normal lives.

Institutions for the aged, both public and private, are improving, changing from mere custodial centers to centers offering many programs and activities even for the chronic invalids. We are learning to discard the term "incurable." The home for the aged maintains apartments, finds foster homes and furnished rooms, correlates its work with health, visiting nurse and housekeeping services, and makes referrals for hospital care.

By working with public organizations, private agency programs may be vastly extended. Continuation of public assistance payments helps to support the private agency. None of the private agencies could maintain their programs without public assistance payments to those who are destitute.

In New York, a Mayor's Advisory Committee for the Aged, composed of leaders in both private and public welfare fields, is concerned with the problems of the aged generally. This correlation on the basis of equality and mutuality in planning for the aged is an outstanding example of the interrelationship of both for the benefit of all.

Hospital and Institutional Care

By A. P. MERRILL, M. D.,
Superintendent, St. Barnabas Hospital, New York City

Among our most effective tools for care of the geriatric patient in modern society are hospitals and related institutions. However, they have not been advantageously employed compared with their utilization in acute medical conditions. The hospital can play an ever-progressive role in public health programs by being the center for health and medical care activities concerned with the chronic disease patient.

A reduction in chronic disease would greatly lighten the economic burden in caring for an aging population, since invalidism and disability increase progressively with age. However, it is estimated that by 1980 there will be about 40 million persons with chronic illness in the Nation, a third of whom may need adequate hospital care for diagnosis, treatment, or rehabilitation.

There are three major categories of geriatric patients: (1) the short-term patient with an illness of under 6 months' duration, who ordinarily is subject to rapid rehabilitation, and who is frequently cared for by the general hospital; (2) the long-term patient requiring care for from 6 months to 2 to 3 years, who may make a much slower recovery and who is frequently found in the specialized hospital for chronic diseases; and (3) those patients with extreme handicaps and severe impairments of health for whom the outlook is less encouraging for complete recovery but who can nevertheless make improvements. These patients are generally found in chronic disease hospitals, in welfare institutions, custodial and nursing homes, and even homes for the aged.

In planning community programs for care of these three types of patients, two fundamental principles should be recognized. The first applies to the dynamic concept of the

medical state of patients with chronic disease, who are either getting well or getting worse. Thus, there is a continual interchange among these three basic categories, and a comprehensive community program should provide for appropriate facilities which would enable patients to be transferred to those accommodations most suitable to their medical conditions. The second principle is that medical care for all categories of the chronically ill should be integrated and continuous, so that a person changing from one dynamic medical state to another is not penalized for lack of adequate medical and nursing care.

Chronic Disease Facilities

There are at present about 127,500 hospital beds for the chronically ill. In addition, it is estimated that a quarter of a million geriatric patients are housed in many other types of institutions, including nursing homes, welfare institutions, and the like, where the quality of medical care may not always be adequate and where the program may fail to meet modern standards. It is estimated that during the next 15 to 20 years some 300,000 beds will be needed for general categories of chronic illness, about 175,000 of these for active medical care and 125,000 for related care.

Aging and chronic disease are not synonymous, but there is a large interrelation which should be considered. Moreover, aging complicates chronic illness. The care of the geriatric patient in modern society requires the development of extensive community and institutional resources under both governmental and voluntary auspices; integration and control programs should be established through both types of agencies. Every State health department should have a division of geriatrics or chronic disease control.

The chronic disease hospital should be a center for professional and public education, prevention, and research, as well as for new advances in care and treatment. It should also be the center for the training of professional and auxiliary personnel and for development of administrative leadership.

A community of 100,000 people would require a 450-bed chronic disease facility—200 beds for active medical care and 250 beds for the custodial, domiciliary, or infirm aged. Such a facility could be operated independently, in a physical sense, or integrated with an existing general hospital. There is not just one pattern of hospital care for the geriatric and chronic disease patient that will fit every conceivable situation. Each community should study its individual needs and act accordingly.

Methods must be found for financing the cost of hospital and institutional care for the chronically ill and infirm aged. Voluntary and private insurance programs should be broadened and extended to cover long periods of sickness and disability, which currently are excluded. Amendments to the Social Security Act are feasible, as well as medical assistance programs from Federal, State, and community sources. The economic aspects of the problem are momentous and upon their solution largely depends the satisfactory outcome of all health, medical, and related problems.

Health Services for the Aging in Saskatchewan

By FREDERICK D. MOTT,
M. D., Health Department
of Saskatchewan, Canada,
LEONARD S. ROSENFELD,
M. D., Division of Public
Health Methods, Public
Health Service, and MAL-
COLM G. TAYLOR, University
of Toronto

In the last 7 years the Province of Saskatchewan has developed a wide range of health services, including government-sponsored hospital care, tax-supported care of cancer cases, comprehensive medical and hospital services for recipients of public assistance, compulsory medical care insurance in the Swift Current health region, a grant-in-aid program for hospital construction, and an air ambulance service.

Health services for the aging in Saskatchewan have developed as part of the general community pro-

gram. Nevertheless, of all groups in the community, the aging benefit most from the values of organized health services. For the aging, the need for medical services rises sharply at a time in life when income either remains fixed or diminishes.

Three programs which are of significance to the aging are the hospital services plan, medical services for social assistance recipients, and the Swift Current health insurance program. During the 4 years of operation of the hospital plan there has been a substantial increase in the utilization of hospital services. This increase was most marked in the age group 65 and over. In 1950 the average length of stay in hospitals for the group aged 65 and over was 21.6 days compared with 9.2 days for the people under that age. This is a result of numerous factors, including differences in the causes of illness, differences in recuperative powers, and changes in mobility and social environment among older people.

Analysis of the Swift Current health region compulsory insurance program reveals that those over 65 years of age receive a much greater volume of care than those under 65. This is true for office and home care, as well as for hospital care.

The health programs in Saskatchewan are characterized by the reduction of economic barriers to necessary health services, and by a minimum of restrictions. With the removal of economic barriers to care of the aged, it is possible to measure the force of various medical and social factors which influence the demand for and the provision of medical services. It is obvious that aging, with its physical, social, and psychological concomitants, contributes toward a high demand for health services.

The aging, as a group, provide a rich field for the study of medical sociology, not because of problems peculiar to this group, but because many of the physical, psychological, and social ills common to all ages converge toward the end of life, creating some of the most difficult problems in organizing an effective system of health services.

The Normal Precordial Electrocardiogram In the Aged

By O. OLBRICH, M. D., Ph. D., and E. WOODFORD-WILLIAMS, M. D., General Hospital, Sunderland, England

This study is concerned with electrocardiographic changes caused by age and with deviations from the accepted norm of the younger population. Five hundred in- and out-patients admitted during the period of 4 months to the geriatric unit of the Sunderland Group of Hospitals were electrocardiographed and their electrocardiograms analyzed. Fifty young normal subjects (aged 20-40) were investigated under the same basic conditions.

The results showed that in the young the vertical and semivertical positions of the heart predominate, whereas in the aged the horizontal and semihorizontal positions are more common. In the precordial and unipolar extremity leads, P waves are smaller in amplitude in the aged than in the young controls, and with advancing years the percentage of absent P waves increases.

With advancing years more Q waves are found in the precordial lead V3. The amplitudes of the R and S waves do not differ, nor do they differ significantly in the aged as compared with the young controls. The sum of R in V5 and S in V1 representing the left ventricular potential and the sum of R in V1 and S in V5 representing the right ventricular potential do not change with advancing years. The QRS duration is longer in the aged than in the young. The ventricular activation time differs slightly in the aged when compared with the young controls. RS-T depressions in the left precordial leads, especially in V4 and V5, were found in 11 percent of the cases. The amplitudes of the T waves decrease with advancing years. The transitional zone depends on the rotation of the heart around its three axes. The PR interval does not change with advancing years and the QT ratio increases

with age, but not above the upper limit of the normal.

Electrocardiographic Patterns

The heart, fixed in the thoracic cavity by the great vessels at its base and supported in this position by the lungs and diaphragm, might rotate, displaced, with the apex forwards or backwards. In the aged, additional factors play an important role with regard to the position of the heart: alteration of shape of thoracic cavity, senile atrophic emphysema, the lower position of the diaphragm, and the tortuosity and elongation of the aorta.

Thus, spatial changes could be responsible for certain electrocardiographic patterns encountered in the aged. As evidence for this, we have taken tracings with the patient in the supine and recumbent positions and by rotating his body at different angles were able to produce Q waves, shift of the transitional zone, and increase or decrease of the amplitudes of the R and S waves in both unipolar and precordial extremity leads.

From the above we draw the conclusion that the decrease or increase of the amplitudes of the different waves and deflections is not due to change of action current caused by age but simply expresses the distance of the exploring electrode from the heart. We do believe that the action current does not change with advancing years.

Health Status and Health Requirements of An Aging Population

By GEORGE ST.J. PERROTT, M. A., MARCUS S. GOLDSTEIN, Ph. D., and SELWYN D. COLLINS, Ph. D., Division of Public Health Methods, Public Health Service

The number of persons aged 65 and over is increasing rapidly, both in absolute numbers and in relation to the total population. This paper reviews the health status of this

group, measured by the prevalence of illness and the receipt of medical care, and gives estimates of future national trends in volume of illness and medical care in an aging population. The data are based on the National Health Survey of 1935-36, supplemented by the morbidity studies of the Eastern Health District of Baltimore during the period 1938-43.

In the general population sampled, the annual case rate for chronic disabling illness was approximately one-fourth the rate found among persons aged 65 and over. For the average person in the older group the period of disability from chronic illness during the year was more than four times as long as that experienced by the average person in the general population.

The so-called degenerative diseases (mainly cardiovascular-renal disorders) are responsible for nearly one-third of the annual disability rates among the older age group, but account for less than 10 percent of the rate among the general population. Among those aged 65 and over, heart diseases head the list of 10 leading causes of disabling illness and of days lost because of disability.

Future Medical Care Needs

Projecting these findings into the future, the number of disabling illnesses lasting seven consecutive days or longer may be about 25 percent higher in 1960, and more than 40 percent higher by 1975. Days lost annually from disability will rise 30 to 40 percent by 1960 and even higher by 1975. As a result of both increase in population and increase in the number and proportion of the aged, the future thus will bring increasing demands for the services of physicians, hospitals, and nurses.

In 1935, physicians' services for persons aged 65 and over with cardiovascular-renal conditions totaled 7.3 million visits annually. If the same rate of visits is applied to the 1975 population of the United States, the comparable annual total may reach 18.7 million visits. In 1975, more than 25,000 hospital beds will be needed for these conditions alone by persons aged 65 and over, on

the basis of use in 1935. In that year, about 10,000 beds were used for cardiovascular-renal disorders among this age group.

Advances in medical knowledge and techniques, changes in the incidence, prevalence, and severity of illness, and economic factors that may alter earlier patterns of utilization of medical and other health services may well require modification of these predictions. Despite these qualifications, a few conclusions seem inescapable. Larger numbers of people (especially women) will live to an age in which their health status will require expanded resources to meet their needs for services of physicians, nurses, and other health personnel, and for hospital care. Increasingly, medical, hospital, and nursing services will be concentrated on the chronic diseases. Control of these diseases would greatly reduce not only the time lost from disability but also the patient load on hospitals, nurses, and physicians.

Organized Community Planning for Old Age

By PHILIP W. SWARTZ,
Executive Secretary, Community Council of Bridgeport and Eastern Fairfield County, Conn.

To what extent are American communities utilizing and applying present knowledge concerning gerontology to serve the older portion of the population? A questionnaire survey yielded responses from 155 community areas, with over 72 percent of all areas of 75,000 or more listing an organization engaged in social planning. This represents 44 States. An analysis of some of the responses follows.

Questions and Responses

"Do you have a committee in your community concerned with over-all planning for old age?" About one-third of the communities had operating committees and an additional one-sixth had plans for formation of committees. Middle-sized cities

showed greatest activity; cities with over 1,000,000 population had only a 75-percent coverage; the lowest rate was found in cities of smallest size. Although most communities had one or more services, many have been operating without much change for a long period.

"What specialized programs and facilities have been developed in your community?" The largest number of community areas were engaged in recreation. Following, in order, were homes for the aged, educational programs, hospitals, special and counseling services, and employment and vocational advice. Only six community areas mentioned housing to serve the needs of the aging.

"Who pays for what?" Of the 485 facilities and programs sponsored in 137 urban areas, 32.5 percent were operated by voluntary agencies; 28.6 percent were tax supported; 16.7 percent were operated by religious bodies; 12.2 percent, by clubs or independent organizations; 4.5 percent, by member payments; 4.5 percent, by schools; and 1.4 percent, by commercial businesses.

The greatest community needs were listed in order of importance: housing and living arrangements, employment services, public relief, visiting homemaker service.

"What difficulty is encountered by old people in obtaining employment in a normal labor market?" Difficulty increased with age in both normal and defense labor markets, but to a lesser degree in the defense labor markets.

"What are the chief attitudes in your community toward old age, and what changes have occurred over the past decade?" In a considerable number of areas, the thinking of the community and the attitudes of employers are now favorably disposed toward considering the older person as an individual. Many areas felt that the development of retirement plans and insurance requirements have helped to withhold application of some favorable attitudes in the employment market. Considerable progress made during World War II in the attitudes of employers has been maintained.

Evaluation

A large number of communities have made considerable progress and some are displaying imagination and interest pointing toward major contributions. There are fewer bright spots where frontier and experimental services are being sponsored. A great lag exists between newer knowledge that has been developed on basic needs and application of such findings. Many programs are not suited to community needs. Great gaps exist throughout the country, with housing a pressing need for all sections and in all areas. Improvements are essential in services for employment, health, specialized home care, personal counseling and adequate financial allowances for the dependent and partially dependent.

Finally, the investigation emphasizes that society has in no substantial way recognized the responsibility for meeting psychosocial needs that accompany the later years of life.

Housing of the Aged, 1950

By LEONARD S. SILK, LL. B.,
Division of Housing Research, Housing and Home Finance Agency, Washington, D. C.

To date there has been a lack of a factual, over-all picture of the existing housing characteristics and living arrangements of older people in the United States. The absence of such information has made it virtually impossible to qualify the housing needs of the aged for the Nation as a whole and to relate these needs to those of the rest of the population. The tendency has been to concentrate research on the welfare and medical aspects of housing, with too little attention given to the economic dimensions of the problem.

In the hope of remedying this situation, the Housing and Home Finance Agency has analyzed special

tabulations of data drawn from the housing census of 1950. The survey, based on preliminary data, of a national 1-in-a-1,000 sample of the American population, covers the housing circumstances only of those aged persons who are heads of households, not those who live as dependents in families headed by younger persons.

With the aged defined simply as those over 65, the total number of such persons living in urban or rural nonfarm housing in 1950 was 10,570,000. It is estimated that at least 80 percent of all persons over 65 maintained independent households.

Home Ownership

The percentage of home ownership is higher among persons over 65 (68.2 percent) who are heads of families than for the general population (53 percent). However, older people own less valuable structures than do the population generally. Those older people who are renters pay lower rents than the rest of the population. Persons over 65 tend to have larger dwelling units than the younger population. But more households headed by older persons were small—two persons or less. As a result, there is far less overcrowding among households headed by older persons than for the population as a whole. On the other hand, the condition of the housing in which the older groups live is below average.

Characteristics of Housing

In general, the aged tend to occupy relatively more very low-rent dwelling units and low-value structures, and their housing is relatively more dilapidated and deficient in plumbing facilities. However, overcrowding is not a particular problem for older people. Housing for older people is shaped and characterized by the following: The aged receive less income, have smaller families, and occupy older dwellings in older neighborhoods than do other groups in the population.

Geriatrics:

General Considerations

By MALFORD W. THEWLIS,
M. D., Thewlis Clinic, Wakefield, R. I.

Favorable economic conditions, better hygiene, medical and surgical advances—especially the use of antibiotic substances—have increased the national life span. There are many problems facing us in caring for the older population. There are fewer nurses and fewer hospital beds. At the same time there is an increase in chronic illness, especially since people live longer.

Perhaps the best approach to the problem is to keep the aged population ambulatory as much as possible. This can be accomplished by better hygiene, improved nutrition, and adequate housing.

The physician can keep older patients active and working by treating them in his office. Once they get into an institution they are likely to remain there. Already there are postgraduate courses in practical office procedures for physicians. More efficiency will enable the physician to treat these patients in his office or in their homes, and thus relieve the congestion in institutions. Merely instructing the patients on proper nutrition helps them to ward off illness. It is amazing how much better many older people feel when they have an adequate intake of ascorbic acid, calcium, and proteins.

Many problems of advancing years must be solved by clinicians. They deal with the patients under conditions as they exist. Their experience enables them to guide social workers, physiotherapists, hospital superintendents, and others active in the field of geriatrics. On the other hand, preclinical medicine must be increasingly practiced by the medical profession.

Medical and Social Problems in England

By R. E. TUNBRIDGE, M. D.,
Department of Medicine,
University of Leeds, Leeds,
England

One of the features of the present century has been the change in the age composition of the population in almost every country. In the United Kingdom today, approximately 1 in 7.5, or almost 14 percent of the population, are of pensionable age, that is, men over 65 and women over 60 years of age. Between one-fifth and one-sixth of the population will be of pensionable age by 1980. Taking into account that one-fifth of the population will be composed of children under 15 and that many married women will be outside the labor force, it would appear that less than 50 percent of the population will have to support the entire population.

Pension Plans

Provision for retirement is from two sources, pension schemes where the amount of pension is based upon previous earnings, and the flat rate which is available to all other insured but not self-employed workers. In addition, old age pensions are available to all people over 70 provided their income does not exceed two pounds (\$6) per week. The cost of the limited pension scheme now takes more than one-tenth of the national budget. In 30 years, if money retains its present value, the pensions will cost at least one-fifth of the national budget. These assessments do not take account of the cost of other social services for the aged.

Increased methods of production may help to remedy the situation, but the obvious solution is to abolish full retirement at the present early age of 65 for men and 60 for women and to encourage part-time work as long as possible. This is desirable from a medicosocial as well as an economic viewpoint because early retirement frequently leads to a sense of not being wanted,

uselessness, and loneliness, with serious consequences to the health and happiness of the retired person.

Medical Care

The change in the age composition raises many fundamental medical problems. It cannot be too often stated that disease in the elderly is not invariably chronic illness. Several recent surveys in the United Kingdom have shown that the common disorders in persons over 70 requiring hospitalization are mental disorders, arthritides, vascular degeneration, incontinence, and bronchitis.

Minor medical maladies and social factors, if not given sufficient attention, can hasten decline. Although sickness in the elderly does not exhibit entirely new disease forms, the reaction of the older patient to illness does provide many medical and social problems. It is often impossible to separate the medical from the social problems, and both must be assessed and adequately met. Adequate care for the aging thus demands a reorientation in medical teaching among doctors and nurses.

Intensive Home Care Of the Chronically Ill

By LOUIS UDELL, M. D.,
Medical Director, Intensive
Home Care Plan, visiting
Nurse Society of Philadelphia

Because of the limited number of hospital beds available and the very apparent increase in the incidence of chronic diseases, especially in the aged group, the problem of caring for these patients is becoming more acute. Home care seems to be the answer for many persons who do not need active specialized care.

Philadelphia has had an intensive home care plan for the chronically ill in operation since April 1949. It was developed in response to organized community demand to determine whether medical and supportive services for chronically ill patients in their own homes and under the care of their own visiting phy-

sician would lead to maximum improvement at less expense than through hospital and institutional care. During the 2 years it has been in operation (in a section of the city with a population of 325,000), the plan has cared for 110 patients, about half of whom were over 65 years of age. Services have been offered on a visiting basis at a frequency determined by the need and have been coordinated by a community public health nursing association. These services include medical, nursing, physical therapy, occupational therapy, nutrition, speech training, and housekeeping care, supported by social case work and mental health consultation. The team approach has been used throughout with careful admission review and regular progress conferences. Referrals have come from all hospitals and a large number of private physicians in the area.

This plan, though patterned after the Montefiore Hospital home care plan, differs from it mainly in (1) control of the patient, (2) home conditions, and (3) administration. Patients remain under the control of their own private physicians, rather than under the direct care of the hospital. Unlike the hospital plans, ideal home conditions do not enter into the decision to accept a patient. Finally, the hospitals in the area have no direct voice in the administration of the plan, although they do refer their chronically ill patients and provide necessary laboratory or X-ray services, or medical and surgical consultation, on a fee basis.

The net cost of the plan for two and a quarter years has been \$25,439.75. It has cost the community approximately \$3 each patient-day.

The reaction of the hospitals and the private physicians in the area to the plan has been very favorable. Moreover, the patients and their families have benefited considerably. Improvements have been noted in conditions formerly believed to be static or hopeless.

This program is suggested as one approach to the problem of care for older persons with chronic illness who wish to remain at home. Consideration of the organizational pat-

tern, the relationships involved, and the costs of promotion and operation leads to the conclusion that such a plan can be repeated in a wide variety of communities.

Needs for Economic Security in Old Age

By EDWIN E. WITTE, Ph. D.,
Chairman, Department of
Economics, University of
Wisconsin

Two main points are made as antidotes to popular impressions: First, adequate economic means, although not all that is needed, are essential for a happy old age. Second, many different approaches are needed to insure adequate income in old age. Specifically, on the latter point, increasing employment opportunities for older people are not a cure-all for the economic problems.

Economic Problems

Increased attention to noneconomic problems which the gerontological movement has produced may minimize the importance of economic issues. Although this recent interest is to the good, it may obscure the important truths that many older people lack economic means for decent existence. Prolonging life by conquering disease does not of itself solve the problem of how people will live. For the great majority of people, old age is a time of reduced income and, for many, complete cessation of earnings.

Although many costs decrease in the older years, some increase with age, notably costs of medical and related care. Also, old age is becoming a progressively longer pe-

riod for many people—average life expectancy for men at 65 is over 13 years and for women, about 3 years longer, more than one-fourth as long as the so-called productive period of life.

Just as for most people, employment is the best way to provide economic security for older persons. But, many older people cannot work full time or at all, and those who can work cannot be readily fitted into new jobs. Nearly half cannot work by reason of physical incapacity. The present enthusiasm for increased employment of older people is most laudable, but the entire problem of economic support cannot be answered by finding employment for older workers. Women now exceed men in this age group and their percentage is rapidly increasing. The proportion of older women workers has increased but is still below 10 percent. Even maintaining the present percentage of men who are gainfully occupied—45 percent—will necessitate the employment of many more older people, as their number is increasing so rapidly.

Support for Older People

We know very little about how older people actually get their livelihood. It is clear that many older people have to live very skimpily. We must find out why some older people are in need while others are getting along very well economically. Two factors seem mainly to account for this difference: earnings received before age 65, and employment or lack of employment after 65. Back of these are other reasons for want in old age: unemployment, long serious illness, disabilities, loss of savings and their declining value.

We also know little about the savings of older people. Although

savings have greatly increased during the last decade, certain forms of savings have greatly shrunk in value.

We should also know more about the extent of aid from children and the significance of industrial pensions which have been very much in the limelight in recent years.

There is great need for more research and information, but likewise for acquainting the public with facts already known and presenting these facts in the proper perspective. Among these are the defects in the present Government systems: the old-age assistance program anomalously gives older people larger payments than are provided on the average under the contributory insurance system.

Conclusions

In stressing defects in present programs for economic security, progress made in the last two decades must not be overlooked. Older people are better off economically than they were during the depression and, quite likely, than during the prosperous twenties. But these programs have hardly kept up with changing price levels and improvements are necessary.

Increased attention must be given to social security and to the economic aspects of the aging population. The prevailing ignorance on these aspects is astounding in view of the immense amount of discussion. This may be one consequence of the gerontological movement. It may lull people into thinking that the economic problems of old age have been solved if only the employment opportunities of older people are increased. This would be most unfortunate, because it is clearly false.

Therapy With Cortisone

By C. PAUL SILIRIE, M. D.

Two years have elapsed since Hench and associates published their preliminary observations on the use of cortisone in the treatment of rheumatoid arthritis and rheumatic fever. How far have we progressed since then? What is the current status of cortisone as a weapon against disease? What are its limitations?

Response to Cortisone

In this brief period, it has been learned that cortisone is capable of exerting certain fundamental physiological effects associated with increased adrenocortical activity. Among these are: diminution of fibroblastic proliferation; suppression of fever, local inflammatory manifestations, and pain; inhibition of certain allergic processes; increased excretion of potassium; retention of sodium and water; and production of various endocrine dysfunctions.

These findings encouraged many clinical investigators to use cortisone in the treatment of a wide variety of diseases. However, this discussion will be limited to diseases responsive to cortisone therapy and about which opinion seems to have crystallized to some extent. In some disturbances the results have been excellent, even dramatic; in others the effects have been variable, but in some instances the benefits have been transient (see table).

Need More Facts

Although phenomenal advances have already been made in research relating to the chemistry

Dr. Silirie of Rahway, N. J., is associated with the medical division of a major manufacturing chemist. He has brought this paper up to date from material presented at the 1951 New York State Department of Health Annual Conference.

and pharmacology of cortisone and the adrenocorticotrophic hormone, ACTH, of the pituitary gland, many large gaps still exist in our knowledge of these hormones. Some of these gaps will be bridged when we have learned more about the following fundamental considerations:

1. The interrelationships of the pituitary, the adrenals, the other endocrine glands, and the various other tissues of the body.
2. The histopathology of the pituitary and adrenal glands of patients with rheumatoid arthritis or other diseases in which cortisone or adrenocorticotrophic hormone is effective.
3. The functions of these hormones in normal persons and in patients with rheumatoid arthritis or other diseases known to respond favorably to exogenously administered hormonal agents.
4. The modes of action and interaction of these substances.
5. The metabolism of cortisone—its absorption and fate in the body.

Other Questions Remaining

Certain refinements in our currently available laboratory tests and the development of newer procedures will undoubtedly help us in answering many of the following practical but perplexing questions:

1. How much endogenous cortisone or adrenocorticotrophic hormone does a normal person produce daily?
2. How much is produced by persons under stress and how much by patients suffering from diseases benefited by the exogenous administration of these hormones?
3. Do all patients suffering from diseases responsive to cortisone or adrenocorticotrophic

Response to cortisone in various diseases

Beneficial effect often dramatic	Results thus far encouraging	Transient beneficial effects observed
Rheumatoid arthritis Still's disease Rheumatoid spondylitis Psoriatic arthritis Acute rheumatic fever Acute lupus erythematosus disseminatus (early or late) Periarteritis nodosa (early) Addison's disease Various allergies: Bronchial asthma Hay fever Angioneurotic edema Drug sensitization Serum sickness Exfoliative dermatitis Pemphigus Inflammatory eye diseases Panhypopituitarism Adrenogenital syndrome (due to congenital adrenal hyperplasia)	Dermatomyositis Psoriasis Retrolental fibroplasia Agranulocytosis and certain forms of anemia (hemolytic, aplastic, megaloblastic)	Scleroderma (early) Alcoholism
	Results encouraging but may be variable	Effects transient, ultimate prognosis unaltered
	Acute gouty arthritis Ulcerative colitis Regional enteritis Nephrotic syndrome Pulmonary granulomatoses: Sarcoidosis Silicosis Berylliosis Purpura hemorrhagica (thrombopenic)	Acute leukemia (lymphocytic or granulocytic) Lymphosarcoma Chronic lymphatic leukemia Multiple myeloma Hodgkin's disease

hormone have inadequate adrenocortical reserve?

4. How much exogenous adrenocorticotrophic hormone is required to produce a given amount of cortisone or cortisone-like hormone?

5. What is the time-dose relationship between exogenously administered cortisone or cortisone-like hormone and the amount available in body tissues during a given period?

6. What is the cortisone threshold in the various diseases, and what dose is required to produce beneficial effects without undesirable side reactions?

Thus, it appears that although cortisone is capable of producing excellent—even dramatic—benefits in many patients suffering from diseases which heretofore have proved stubbornly refractory to older methods of treatment, it is quite obvious that a full understanding of the manner in which these substances influence various physiologic or pathologic states remains to be attained. Therefore, until more knowledge of these agents is acquired, we must proceed with caution, accepting calculated risks, in our attempts to develop safe and effective methods for their use.

Undesirable Effects From Cortisone

From our experience to date with cortisone and adrenocorticotrophic hormones, we have learned that these agents may at times produce undesirable effects. Therefore, before administering these hormones, the physician should weigh the possibility of producing these effects against the anticipated beneficial results.

A number of relative contraindications to the use of these hormones must be kept in mind. These are of greater or lesser importance, depending upon the nature of the disease (see list). Thus, in general, caution should always

Cortisone therapy—Relative contraindications

Psychotic or prepsychotic personality
Tuberculosis or other serious infections
Congestive heart failure (except that resulting from acute rheumatic carditis)
History of a previous thromboembolic episode
Bacterial or viral infections unless adequate amounts of the proper antibiotics are employed concurrently
Angina pectoris
Duodenal or gastric ulcer
Renal disease
Osteoporosis
Pregnancy
Diabetes mellitus
Hypertension

be exercised with the use of these products in patients having known infection or possessing psychotic tendencies. In the former, these hormones interfere with the immune response and may mask the signs and symptoms of the infectious process; in the latter, a frank psychosis may be precipitated.

The use of cortisone has produced remarkable clinical results in a wide variety of diseases. Even more remarkable is the fact that most of these diseases have heretofore proved unresponsive to other agents. However, even though cortisone is capable of controlling the manifestations of many diseases, its continued use may also produce certain undesirable effects. It cannot be overemphasized that side effects should be considered as evidence of excessive hormonal activity and not as truly toxic effects of the hormone. Moreover, these effects are completely reversible following discontinuation of therapy.

Nevertheless, injudicious use of these potent hormonal agents, like misuse of many commonly employed hormones such as insulin, thyroid substance, or testosterone, may result in certain untoward effects. In the case of cortisone, the physician should respect but not fear the side effects. Dosage has an important bearing on these phenomena. Expressed in simple terms, the problem is to determine the maximum dose compatible with a minimum of undesirable effects. Although much has been learned about the side effects, the problem has not yet been completely resolved.

The Future of Cortisone

Although we are fully cognizant of the therapeutic value of cortisone, this hormone is becoming increasingly more important as an investigative tool in clinical research. We may look upon cortisone as a key which may serve

to unlock the door to a better understanding of many disease processes, the mechanism of which still remains obscure. In fact, many of the pages in our textbooks dealing with the etiology, pathogenesis, pathology, diagnosis, and treatment of many conditions may have to be reviewed and rewritten in the light of newly acquired knowledge made possible by clinical and laboratory experiences with cortisone.

One may ask, "What about the future of cortisone as a therapeutic agent?" "How long will it be before we can make categorical statements as to its definitive value in a specific disease?" The answers to these questions will come only after patient and careful study on the part of physicians, public health organizations, and allied professions. This teamwork may also aid in the realization of the greatest of all hopes—the ultimate defeat and eradication of disease.

High Incidence of Measles Reported

The incidence of measles in the United States this season is running far above that for the same periods 1 year ago. The total number of cases reported from September 1, 1951 (the seasonal low week) through January 12, 1952, is 78,085, as compared with 41,128 for the same period a year ago. The median for the 5-year period, 1946-50, is also 41,128. The incidence is concentrated primarily in the eastern part of the country.

Conjunctivitis in Elementary Schools

By DORLAND J. DAVIS, M. D., and VIRGINIA D. HINES, B. S.

As a part of an epidemiological investigation of conjunctivitis due to bacteria of the genus *Hemophilus*, in Thomas County, Ga., a study of the occurrence of the disease was made in children attending 12 elementary schools¹ accessible to uniform observation.

In this area, as well as in many other parts of the southern United States, acute conjunctivitis is a common affliction of children and is known as "sore eyes" or "gnat sore eyes." Bacteriological studies in Texas (1) revealed the presence of *Hemophilus aegyptius* or Koch-Weeks bacillus (2), and *Hemophilus influenzae* in a significant number of cultures of the conjunctiva. These species have also been found in the current studies in Thomas County.

In addition to the bacteriological studies of cases to be reported later, an effort was made to assess the importance of conjunctival disease among children attending the schools of this region. Principals and teachers of the 12 schools, 6 white and 6 Negro, were asked to keep records of absenteeism due to conjunctivitis and of children with conjunctival symptoms attending schools. The analysis of these records forms the basis of this report.

Thomas County, located in southwestern Georgia, had a recorded population of 33,903 (approximately 45 percent Negro), according to the preliminary figures of the 1950 U. S. census. Agriculture and lumbering are the chief industries. Thomasville (population 14,446, preliminary 1950 U. S. census figures) is the largest town and serves as a commercial center for the area. Observations were made on children attending two of the three elementary schools for white children and both the elementary schools for Negro children in

Thomasville. Most of these children lived in Thomasville proper, but about one-third lived in nearby rural or semirural areas and were transported to school by buses.

Outside of Thomasville nearly all children attend consolidated schools in the various nearby communities and are transported to and from their homes by bus. The study included observations on children attending both white and Negro schools (grades 1 to 11) in four other Georgia communities: Boston (population 1,032, preliminary figures 1950 U. S. census); Barwick (population 500, unofficial census); Meigs (population 1,083, preliminary figures 1950 U. S. census); and Ochlochnee (population 450, unofficial census). Most of the children attending these schools live in rural areas and the communities themselves are small or semirural. No studies were made of the 8 other consolidated schools and 11 one-room Negro schools in the county.

Collection of Data

The data were collected under the direct supervision of a Public Health Service nurse who was participating in the field work of the investigation. The information was actually recorded by the teachers of each room on forms specially prepared for this phase of the study. These forms were collected at 3-week intervals during the school term (October 10, 1949, to December 19, 1950), thus providing records

Dr. Davis is with the National Microbiological Institute of the National Institutes of Health, Public Health Service, Bethesda, Md. Miss Hines is with the Communicable Disease Center of the Public Health Service, assigned to the Thomasville Station section at Thomasville, Ga.

¹ One school, the white elementary school of Barwick, was actually located just across the county line in Brooks County, Ga.

Table 1. Conjunctivitis in grades 1, 2, and 3 of 12 selected schools, by month, October 1949 through December 1950

	1949			1950								
	October	November	December	January	February	March	April	May	September	October	November	December
Total enrollment, pupil-days-----	17, 799	38, 643	22, 883	42, 543	38, 504	43, 012	34, 061	30, 492	30, 718	39, 990	36, 682	21, 687

Pupil-days absent presumably due to conjunctivitis, per 1,000 pupil-days of absences from all causes-----	158. 5	75. 9	11. 5	19. 0	9. 2	2. 5	5. 2	2. 9	152. 0	78. 3	20. 8	28. 5
Pupil-days present with conjunctivitis observed in school per 1,000 pupil-days of attendance-----	17. 0	7. 8	2. 0	2. 3	2. 8	2. 7	3. 5	5. 3	16. 7	12. 5	5. 2	3. 4

of more than a year's observations. The teachers were asked to list the name, age, and sex of each child in the room, record each day of absence from any cause, each day of absence due to conjunctivitis, and each day that a child attended school while having conjunctival symptoms apparent to the teacher. This method of collecting information has many deficiencies—the number of different individuals recording the data, uncertainty of the cause of absence, the difficulty encountered by medically untrained persons in determining whether a child had signs of conjunctival disease, and some irregularity in recording data because of the press of teaching duties. A comparison of our records of total absences with the regular school reports of average daily attendance revealed a close agreement, but the records for the incidence of conjunctivitis were probably less accurate. Nevertheless, crude as they may be, the records do serve as an index of the extent of the problem of conjunctivitis in school children of Thomas County.

For analysis, the data were tabulated on the basis of pupil-days experience per month. The total number of children enrolled in a room was multiplied by the number of school days per month to give the total pupil-days of enrollment for that room or grade. The total of pupil-days was corrected by additions and subtractions in number of pupil-days for individuals entering or withdrawing from school dur-

ing the period. Likewise, absences were calculated on number of school days absent for each child. Rates could then be computed in terms of pupil-days per monthly time interval for the desired groupings of grades. Final tables, by months, were made of the experience of children attending the first, second, and third grades, which included those aged 6, 7, and 8 years, and in some instances, especially in Negro schools, some children 9 and 10 years of age. Tabulations of the data for grades 4 to 6 were made on an annual basis only and not adjusted to months because of the small numbers involved.

Analysis of Data

The experience with conjunctivitis in the first 3 grades of the 12 selected schools during the period of study is shown in table 1.

It would appear from the data presented that the rate of absences from conjunctivitis is highest in September and October and declines thereafter. The rate of absence from all causes (table 1) was highest in the spring months, but not of sufficient magnitude to affect significantly the seasonal pattern of the proportion of absences due to conjunctivitis.

Table 2 presents data on the annual "disability" rate, by grades, in the individual schools and in all schools of the study.

The children in grades 1 to 3 were more af-

fected than those in grades 4 to 6, as judged by the rate of absences and of observed conjunctivitis in those attending all 12 schools. Although the data are not presented here, cases were observed less frequently in grades above the sixth and were seen occasionally in teachers. According to these data the rate of absenteeism

due to conjunctivitis was higher in the white schools than in the Negro schools for both grade groupings. This is also true for the observed incidence of conjunctivitis in those attending schools outside of Thomasville but is not evident in the Thomasville schools. Although there does not appear to be a differ-

Table 2. Annual "disability" rate of absence due to conjunctivitis and presence in school with observed conjunctivitis, per 1,000 days of enrollment, January through December 1950

	Annual enrollments in pupil-days	Absent because of conjunctivitis		Present with observed conjunctivitis		Total with conjunctivitis	
		Pupil-days	Rate per 1,000 pupil-days	Pupil-days	Rate per 1,000 pupil-days	Pupil-days	Rate per 1,000 pupil-days
Thomasville white schools:

Total.....	586, 015	806	1. 4	2, 709	1. 6	3, 515	6. 0

ence in absentee rates between schools in Thomasville and outside Thomasville for white and Negro and for the grade groups, a higher rate of observed diseases was recorded for those in attendance at the schools outside of Thomasville. The total rates for conjunctivitis reflect this difference also. Usually the Thomasville school children with the disease in the acute stage were sent home. But in other schools where the children were dependent on bus transportation it was not possible to send them home, and they remained in school.

The figures indicate the extent of the problem. They show that a total of 806 pupil-days of absence were due to conjunctivitis. Also 2,709 pupil-days of conjunctival disease were observed in children attending school in grades 1 to 6 of the 12 schools under observation during 1950.

The records were also analyzed to show the actual number of individual pupils who were absent because of conjunctivitis and who at-

tended school with observed conjunctivitis each month from November 1949 through December 1950, and the total individual attack rate per 100 pupils enrolled. These are presented in table 3 for the first three grades by school groups. In preparing these data, individuals with conjunctivitis were counted only once each month. If they were recorded as both absent and present with conjunctivitis, they were counted as absent during that month. The highest attack rate occurred during the month of September in the group including four white schools outside of Thomasville when about 1 of every 3 or 4 pupils was affected by the disease. In the same month there appeared to be a lower incidence in the Thomasville white schools with about 1 in 10 affected. Negro children were less intensively attacked, and the rate for both races was lower in Thomasville schools than in schools outside Thomasville. Although the rates were highest in all groups in September, October, and November, cases were observed

Table 3. Number of pupils absent because of conjunctivitis, number present with observed conjunctivitis, and total attack rate per 100 pupils enrolled, grades 1, 2, and 3 of 12 selected schools, November 1949 through December 1950

throughout the year. In white schools outside of Thomasville, the rates gradually increased from a low of 1.6 percent in December

1949 to 8.1 percent in May 1950 when the schools closed for the summer.

In a study of absenteeism in New Haven,

Conn., schools, Linde and associates (3) recorded data on absences due to diseases and disorders of the eye for 1927 and for 1948, calculated in pupil-days. Though their data are not strictly comparable to ours because of inclusion of all eye diseases, and are of somewhat different age groupings, they show a very much lower annual rate, 0.30 per 1,000 pupil-days in 1948, including all disorders of the eye, compared to our rate in Georgia, 7.4 per 1,000 pupil-days in grades 1 to 3 and 4.3 per 1,000 pupil-days in grades 4 to 6. This emphasizes the relative importance of the problem in the schools of Thomas County and in other parts of the South where the disease occurs.

Summary

To assess the importance of conjunctivitis as a cause of absenteeism and disability in the school children of Thomas County, Ga., studies were made in six white and six Negro elementary schools of that county from October 1949 to December 1950. An analysis of the records of these studies on the basis of pupil-days experience shows that the highest incidence of the disease occurred during September and October when about 15 percent of all absences in pupil-days was due to conjunctivitis.

When calculated in pupil-days, the rates of absence due to conjunctivitis and occurrence in children attending schools were higher in grades 1 to 3 than in grades 4 to 6 for both white and Negro children and higher in the white schools than in the Negro schools. This does not necessarily reflect differences in numbers of individuals affected. The records indicate also that

there was more conjunctival disease in white schools located outside Thomasville than in white schools in Thomasville, though this is not reflected in the rate of absences due to conjunctivitis. In grades 1 to 6 of the 12 schools under study during the school year 1950, a total of 806 pupil-days of absence was ascribed to conjunctivitis, and 2,709 pupil-days of conjunctival disease were observed in children attending school.

The data do not represent a true incidence of the disease in these school children because of the methods used in the collection of records. But they are useful as an indication of the magnitude of the problem, of the seasonal occurrence, and of the white and Negro incidence in that county.

ACKNOWLEDGMENTS

The assistance and cooperation of Dr. John D. Stillwell, commissioner of health, Thomas County health department, W. H. Rehberg, superintendent, Thomas County schools, and R. D. Blakeney, superintendent, Thomasville city schools, is acknowledged. We particularly appreciate the continuous assistance and interest of the many individual teachers and principals of the 12 schools in which the studies were undertaken.

Birth Registration Has Improved in Past Decade

The proportion of infants without birth certificates has been reduced by three-quarters during the past decade, preliminary results of a nation-wide survey of birth registration indicate. This survey—the second of its kind—found that almost 98 percent of the babies born in the first 3 months of 1950 were registered as compared with 92.5 percent in 1940, when the first national test was made.

The recent birth registration test was conducted by the Public Health Service and State health departments, in cooperation with the Bureau of the Census, Department of Commerce. It involved matching birth certificates with census records.

The primary purpose of the nation-wide test was to measure the completeness of birth registration in States and local areas on a comparable basis. The results will help registrars to spot the problem areas and to determine the reasons for failure to register births.

Ideas

Public health progress depends upon ideas—new, different, better ways of doing things. And it is not only the big things that demand ingenuity, new concepts, unique relationships. The smaller, everyday problems of public health can be and are being met more efficiently, more economically, more usefully and satisfactorily. Large and small jobs worth talking about and worth sharing with colleagues are being done today and will be done tomorrow. Public Health Reports has been asked by a number of public health people to provide a point for exchange of ideas—this page representing the first attempt. Whether it continues is dependent upon the readers. Your comments . . . and your contributions of ideas are welcome.

—The Editors.

Hospital Conferences

GEORGIA. The problem of obtaining better understanding of hospital programs has been approached through a series of regional conferences in Georgia. These conferences are sponsored by the Division of Hospital Services of the State Department of Public Health and in cooperation with the Division of Medical and Hospital Resources of the Bureau of Medical Services, Public Health Service.

The State has been divided into five hospital regions. In each of these a conference of hospital trustees, hospital administrators, and public health personnel devotes an entire day to round table discussions of common problems and their solutions. Special emphasis is placed on the needs of trustees, a group who have not been particularly pressed to participate in health affairs.

Basic subjects are covered in gen-

eral terms by qualified speakers, following which there is spirited discussion and exchange of ideas by the group. Items discussed included medical staff relationships, money, people, and community resources, the latter also covering public relations.

The conferences aim to establish patterns which will enable all groups concerned to arrive at unified action toward health goals and better hospital services.

"Killer Fish!"

LOS ANGELES, CALIF.

*There once was a young larvae
named Harvey,
Who swam near a fish that
was starvey.
Before saying who is ya,
He was ate by the 'busia,
And now Harvey is presarvey
in anchorvey.*

So runs the limerick on the city health department's "Killer Fish!" exhibit which was built for the 1951 Hall of Health at the Los Angeles County Fair.

The feature of the exhibit was several hundred live *Gambusia affinis*, the 1½-inch-long fish with a voracious appetite for insect larvae. The fish were periodically fed live larvae, which were eaten almost instantly upon hitting the water.

On the two side panels of the exhibit were shown clippings from two national magazines describing the year-round Los Angeles mosquito control program, as well as trans-

parencies showing field operations.

In 17 days at the Los Angeles County Fair, it was seen by an estimated 450,000 persons, who asked for, and received, 75,000 free fish to take home for their own private ponds and lakes. The center of the display was dominated by the fish tank and a 2-foot-long wooden fish which continuously leaped at and swallowed an animated larva. In neighborhood distribution during the year, the Los Angeles department gave 78,000 fish to residents for domestic mosquito control, and planted an additional 100,000 in rivers, sloughs, and streams. Routine control work—such as drainage, power spraying (from the department's four fully equipped jeeps), inspections, and mapping of mosquito movements—was also maintained.

The exhibit was designed by the health education division of the department and staffed by the mosquito control section. At the recent annual meeting of the American Public Health Association the exhibit received a citation of merit.

School Nutrition

FLORIDA. Most of the schools of Sarasota and Manatee Counties are participating in a public health nutritional program which goes beyond the school lunch concept. Students who appear to be below par physically, mentally, or emotionally are selected and screened by the teacher, nurse, and physician. Hemoglobin,

Los Angeles City Health Department photograph (by Seibelman).

The Los Angeles City Health Department's County Fair Exhibit

height, weight, and hookworm tests are done periodically.

The public health nurse visits the homes to explain the program and to see that the pupils get enough sleep, rest, recreation, and food. At school pupils are given vitamins with fruit juice or milk daily and a good meal at noon. Some schools provide breakfast when children do not get sufficient food at home.

Infant Measurement

FRESNO, CALIF. Problem: Unsuitable space in health center for measuring infants during well-child conference. Solution: Wall cabinet measuring table utilizing laboratory sink space not needed during clinics.

The baby-measuring table essentially is a wooden wall cabinet frame to which a shelf is hinged. There are folding legs to allow the shelf to be supported by the drainboard but to clear the swing spout of the mixing faucet. A peg board on the front of the cabinet can be used for draining laboratory glassware.

The model was conceived by Mrs. Lois Simpson, a public health nurse, and Mrs. Walter Rhode, and was built by Walter Rhode, construction foreman of the O'Neill Ranch, site of the Fresno County Health Center.

M/S Hygiene—Floating Health Center

ANCHORAGE, ALASKA. A familiar and comforting sight to many residents of southeastern Alaska is the M/S *Hygiene*, floating health center of the department of health. Residents are told in advance when and how long the *Hygiene* plans to be in port so that they can arrange to attend clinics.

The M/S *Hygiene* carries a captain, crew, and chef, and is staffed with a physician, nurse, dentist, X-ray and laboratory technician, and secretary. Staff members meet with community leaders, and in many of the villages, residents have set up

health councils to carry out programs outlined with the help of the *Hygiene's* staff. Programs have covered sanitation, protection of water supplies, isolation of tuberculous patients, and care of the sick in the home.

In addition to regular clinics and chest X-rays, stress is put on prenatal and well-baby conferences, postpartum services, special instruction for midwives, and health education programs for children and adults. Laboratory services, including blood tests, are done aboard ship so that treatment or instructions may be given to the patient before the vessel leaves port. Water samples are also tested during the visit. Reports are furnished to the itinerant nurse for her information in follow-up, and the immunization status of preschool and school age groups is checked.

The M/S *Hygiene*, a converted 114-foot military craft, has been in service since 1945. It is one of five mobile units. These units, the Alaska Territorial Department of Health feels, have proved effective in providing a generalized health service for isolated communities in locating and bringing under treatment unknown cases of tuberculosis, in finding cases needing hospitalization because of crippling conditions due to disease or accident, and in uncovering environmental problems in need of intensive public health service.

Research in Epidemiology of Mental Illness

By R. H. FELIX, M. D., and MORTON KRAMER, D. Sc.

As mental health programs develop throughout the country, we are often confronted by requests from laymen and professional persons alike for a variety of facts and figures. What, for example, is the extent of the problem? How many people in the United States actually are mentally ill? How many mental health clinics do we need? How many psychiatrists? How many psychiatric nurses?

All of these questions are reasonable and important. Yet to none of them can we give a firm answer, based on tried and tested facts.

It may be argued that, since the deficiencies in service, personnel, and facilities in this field are so obvious and so great, why bother collecting data to prove what is already known?

This argument is not valid. In the first place, we have the problem of allocating scarce resources and must find areas of greatest need. The very complexity and vastness of the problem make it imperative that we get the best possible data upon which to base our action programs. Second, as research in this field goes forward on a broad front, epidemiological data are needed, not only to advance fundamental knowledge but also to help us develop more effective treatment and control methods. Our great need is for facts—many facts, accurate facts—that will not only help us learn how mental illness can be brought under control and what staff and facilities are necessary to do this,

but also how such illness can be prevented. Third, facts that we find today will be needed tomorrow as a yardstick against which to measure our progress.

Thus, intelligent planning for an integrated public health attack on mental illness demands adequate epidemiological information. We must have information on the extent of the problem—that is, how many are affected. There are also a great many other things we need to know. What are the characteristics of the mentally ill as a group and as opposed to the rest of the population with respect to such factors as age, sex, race, and occupation? How does mental illness develop in the individual and what factors explain its distribution in the population? What are the constitutional, physiological, psychological, and socioeconomic factors that may be related to cause and course of the illness?

Each of the above questions presents a challenging research problem. Even before we can accurately determine the number of mentally ill in our population, we must first acquire the following kinds of basic knowledge: a clear definition of the entity we are trying to count; diagnostic methods which permit separation of the population into those who have “mental illness” and those who do not, and case-finding techniques that can be used to detect cases of the disease in representative samples of different segments of the population. These are necessary in order to estimate the general prevalence and incidence of the disease with some degree of accuracy and to study its differential distribution by race, sex, age, geographic location, and so forth.

As all of us are well aware, mental illness is not a single entity. Rather we are dealing with a broad variety of disorders, including the functional and organic psychoses, the psychoneuro-

Dr. Felix is director of the National Institute of Mental Health and Dr. Kramer is chief of the NIMH biometrics branch, National Institutes of Health, Public Health Service. This report was presented by Dr. Felix at the annual meeting of the Committee on Mental Health, State Charities Aid Association, held in New York City, May 2, 1951.

ses, and that group of miscellaneous disorders referred to as disorders of character, behavior, and intelligence. For the most part the etiologies of these disorders, which range in severity from the near normal to the far extremes of psychotic behavior, are not known and there are no standard methods for their diagnosis.

We have, of necessity, made various estimates of prevalence, but these estimates are based on data of limited applicability, derived from widely divergent sources such as censuses of patients in mental institutions, other studies of the hospitalized mentally ill, selective service and armed forces data, and community surveys. Although the facts from these sources are widely quoted, it might be well to review them at this time so that, with a better appreciation of their limitations, we can go on to consider progress that is being made in the study of the mass aspects of mental illness and to discuss some areas in which additional work is most urgently needed.

Community Surveys

First we will consider the two most widely quoted community surveys that have been carried out in the United States, one in Baltimore, Md., and the other in Williamson County, Tenn.

The Baltimore survey of 1936, conducted by Lemkau, Tietze, and Cooper (1), was limited to the Eastern Health District, an area about 1 mile square in the eastern part of the city which serves as the field laboratory for the Johns Hopkins University School of Hygiene and Public Health. At the time of the survey, this district had 55,000 inhabitants, one-quarter of whom were Negro. Among the white residents were many families of Hebrew and Czech extraction. The area is principally residential. The income level for both white and Negro families is definitely below the city-wide average.

The case-finding survey was made by searching the written records of some 43 institutions and agencies that deal with mental health problems, including public and private psychiatric hospitals, training schools for mental defectives and delinquents, psychiatric clinics, social agencies, the public school system, the National Health Survey, and the juvenile court. In many

SOURCE: Reference 3, table 3, p. 11.

cases, either a psychiatric diagnosis or a detailed description by a competent social worker was available. Where no diagnosis was given, one was deduced from the written records. No cases were personally examined by the survey staff psychiatrist.

The cases included in the survey were those active on the books of the various institutions and agencies at some time during the survey year. They were classified into 10 major categories: psychosis, psychoneurosis, psychopathic personality, personality disorder in adults, behavior disorder in children, minor or possible disorder in adults and children, epilepsy, mental deficiency, school progress problems without mental deficiency, adult delinquency without other information.

Findings in the Baltimore survey are shown

in table 1. Cases are arranged according to their leading classification. For 1936, the survey year, 3,337 active cases of mental disorder, as defined, were found in a population of 55,129, a 1-year prevalence rate of 60.5 per 1,000. This rate includes epilepsy and mental deficiency as well as psychiatric disorders.

The Tennessee survey was carried out by Roth and Luton (2) in Williamson County, Tenn., a fairly typical agricultural community with an area of 586 square miles and a population of 25,000. One-quarter of the people in this area were Negro, the rest being mostly native white of English or Scotch-Irish extraction.

The project started in September 1935. The staff lived and participated in the normal life of the community so as to become acquainted with all aspects of community life and with various individuals and agencies whose cooperation was essential.

Cases were referred to the survey staff in several ways. Some were reported by physicians, nurses, teachers, clergymen, judges, and others who were in contact with large numbers of residents. Other cases were discovered by staff field workers through their community activities. Still other cases were found by search of institutional records. More than half of the cases were interviewed or examined by members of the staff, which included a psychiatrist, social workers, and nurses. In addition to this general county-wide investigation, an intensive house-to-house survey was conducted in three selected areas.

Approximately 2,000 cases were referred to the survey staff during the 3 years of the study. These cases were followed to determine their status as of September 1, 1938. On that date, 1,721 cases, or 69.4 per 1,000 population, were still residents of the county, as shown in table 2 where they are classified by primary diagnosis.

The range of mental health problems included in this study was about the same as that in Baltimore, although the cases were classified into only seven major groups. Significantly, the case rate for the three districts where an intensive house-to-house survey was made was 123.7 per 1,000 population, twice as high as the rate of 69.4 for the rest of the county. Since the intensive study areas were representative of the entire county, Roth and Luton have con-

Source: Reference 3, table 4, p. 12.

cluded that case-finding methods used for the rest of the county were only about 50 percent effective.

Because of evident differences, the Baltimore and Tennessee survey results are not very comparable. Nor can these results be compared with findings in European countries, where a few surveys have been made. Lemkau, Tietze, and Cooper (3) point out that all of these studies suffer from poor selection of sample populations and insufficient numbers of cases as well as differences in fundamental concepts and differences in diagnosis and classification.

Selective Service and Armed Forces Data

The second widely cited source of prevalence data is the World War II experience of the selective service system and the armed forces.

Selective service experience, as is well known, shows more registrants rejected for mental and personality defects than for any other type. Up to August 1, 1945, some 18 percent of all rejections had been due to these disorders (4).

Further evidence comes from studies on prevalence of medical defects made on a carefully selected sample of registrants who were examined during the period 1940-43. These studies

showed mental illness as the sixth most common defect among all registrants in the sample, with a prevalence rate of 55.8 per 1,000. Among white registrants, mental disease was the fifth most prevalent defect; among Negroes, it was the eighth. The kinds of mental disorders de-

Figure 1. Resident patients in mental hospitals per 100,000 population, United States, 1903-1948.

tected were classified into five major groups, different from the classifications used in either the Baltimore or Williamson County survey. These selective service figures do not include mental deficiency as did the community surveys.

These data have, of course, a number of limitations. The prevalence rates depend upon such factors as the age group examined and the general medical standards prevailing at the time of examination, as well as variations in efficiency of screening for mental disorders at different induction stations (5). They also depend upon the number of voluntary enlistees, probably the more physically and mentally fit, who did not pass through selective service examinations. Other factors were nonexamination of men who did not meet certain educational standards, who had certain obvious physical defects, or who were deferred automatically because of dependency or occupational status. Thus, these rates cannot be applied with any conviction to the entire male population aged 18 to 44.

Armed forces experience, obviously, is even less applicable as a measure of mental illness prevalence in the general population. It applies to a group that was preselected through selective service examinations as well as through

voluntary enlistments. Furthermore, the emotional tensions and the stress situations to which these men were subjected varied greatly in intensity, nature, and duration. An indication of the magnitude of the problem, insofar as the armed forces are concerned, is derived from the number of disability discharges because of neuropsychiatric reasons during World War II. Of 980,000 disability discharges from the Army during the period December 1941 through December 1945, 43 percent were for neuropsychiatric reasons (6).

Patients in Mental Hospitals

The most detailed data available on the mentally ill are derived from mental hospital records. These relate only to persons who are sufficiently ill to warrant admission into a hospital for long-term care of psychiatric disorders.

At the end of 1948, the most recent year for which data are available (7), more than 554,000 patients were resident in mental hospitals. This is a rate of 382 per 100,000, more than twice the rate of 186.2 found in 1903, the earliest year for which reasonably comparable figures are available (fig. 1). Throughout this period, the great majority of these patients have been cared for in the State hospitals, where 85 percent of long-term mental hospital patients now reside.

First admissions to the long-term mental hospitals have been used as an incidence index for the more serious mental disorders. They also give us information about age differences in first admissions for different types of disorders (fig. 2).

For example, in youth and early maturity, schizophrenia and manic-depressive psychoses are the predominant diagnoses at first admission, these reaching their peak in the late thirties and early forties. They are succeeded in importance during the next decade of life by the involutional psychoses. General paresis and alcoholic psychoses are also important at this period. In the sixties, psychoses with cerebral arteriosclerosis and senile psychoses assume prominence, and these mental diseases of the senium continue to rise in frequency until the end of the life span.

Although admissions of senile cases have increased greatly in the last decade, the resident population of most mental hospitals consists largely of a slowly accumulated residue of schizophrenic patients who are admitted during youth or early maturity and stay, in many cases, until the end of the life span. The turnover of senile cases is very high, mainly because of their high death rate. These facts are illustrated by data from New York State, which show the percentage distribution by selected diagnosis of first admissions, discharges, deaths, and patients resident at the end of 1947 (fig. 3). These New York State data, together with material specially gathered in other States here and there, add considerably to our knowledge of the hospitalized population.

Another type of study of the hospitalized population is concerned with the ecology of psychoses. Faris and Dunham (8) have studied hospitalized psychotics in Chicago in relation to various socioeconomic factors, and a few other investigators have made similar studies in other areas (9). These studies have indicated:

New York State Department of Mental Hygiene.
 Figure 3. Percent distribution of patients by selected diagnoses, New York Civil State hospitals, 1947.

1. All types of mental disorder tend to show a similar pattern of residence concentration in and around the central business district, with rates declining toward the periphery.
2. The schizophrenia rates characteristically show this typical pattern, while manic-depressive rates show much more scatter throughout the city.
3. Persons residing in areas not primarily populated by their own ethnic or racial groups show much higher illness rates than do the numerically dominant group.

All such studies of the hospitalized population suffer from several limitations. Only persons with severe disorders are hospitalized. Also, the adequacy of hospital facilities varies from State to State. Evidence of this is seen in the waiting lists maintained by the already overcrowded State hospital systems. Another indication is the wide State-to-State variation in resident patient rates, ranging in 1948 from 1.7 per 1,000 population in New Mexico to 5.5 in New York State. The third fact is that we do not know the relationship between the number of persons with a specific disorder who are hospitalized and the number of persons with a similar disorder in the population who are not hospitalized.

Before the hospitalization rate can be used to indicate the prevalence of a specific disorder in the general population, this relationship must be determined. In the Baltimore survey, only 75 percent of the psychotic cases were hospitalized at any one time, and the Tennessee survey indicated that in Williamson County only 50 percent were hospitalized. Because of the

Figure 2. Age specific first admission rates, per 100,000 civilian population, for selected diagnoses, to State hospitals for mental disease, United States, 1948.

different characteristics of the populations in which the surveys were made, including attitudes toward hospitalization and separation of individuals from their families and variations in availability of psychiatric services and hospital beds, it is difficult to determine what these findings mean with respect to unhospitalized psychotic cases in the rest of the United States. Nevertheless, even imperfect data may be helpful, as in the Framingham tuberculosis study of 1917 (10) which revealed nine active cases of tuberculosis in the population for each annual death from that disease. Although improved case-finding techniques have revised this estimate, this type of ratio derived from early studies has proved highly useful in public health work on tuberculosis control.

In short, existing data on the extent of mental illness have distinct limitations. We cannot say with any assurance just what proportion of our population is afflicted or how frequent are the various types of disorder.

To collect better information, some formidable methodological problems must be solved. For example, much work must be done in standardizing diagnostic procedures so as to get clearly definable and truly comparable groups of cases. Practical case-finding techniques must be developed, such as screening methods for finding persons in the general population, even those not under psychiatric care, who actually have detectable mental illness. In the course of seeking answers to these problems, a great many other facts will be found which will have high value in the development of adequate facilities for psychiatric diagnosis and care, and for learning what kind of preventive services are needed and are feasible.

Studies in Progress

Progress is being made. A number of extremely promising projects have been started in recent years. Each represents a team effort in which the psychiatrist, psychologist, social scientist, and other research personnel are combining their skills and knowledge. Among the most interesting are the following studies.

The Stirling County project, under the direction of Dr. Alexander H. Leighton of Cornell University, is an intensive study of a county

in Nova Scotia. The research has three major objectives. One is to develop case-finding techniques for all types of mental disorder. Data will be obtained on persons hospitalized for psychosis, severe psychoneurosis, or psychosomatic complaints. A clinic is being set up to do some follow-up of hospitalized patients as well as to examine patients referred by physicians, clergymen, schools, police, unemployment insurance offices, and health, welfare, and other local agencies. A second objective is to evolve screening tests applicable to the general population which will serve as a check on the completeness of other case-finding methods. The third objective is to map various types of social stress in the community and to study the relationships between such stresses and the appearance of mental illness. To eliminate the effect of biases and preconceptions, one team of investigators is doing the case finding and another is mapping the stresses. The two series of data will be merged and correlated to determine existing relationships.

The Yale project is the joint endeavor of a psychiatrist and a sociologist, and is being aided by the National Institute of Mental Health through a research grant. Its directors, the two Yale faculty members, Dr. F. C. Redlich and Dr. A. B. Hollingshead, are investigating interrelations between social structure and mental illness. In connection with this problem, they are taking a census of persons in a metropolitan area receiving psychiatric treatment, that is, persons in mental hospitals, attending mental hygiene clinics, or under private psychiatric care. In addition, the social structure of this metropolitan area is receiving intensive study. Correlations will be sought between these social variables and the frequency and types of mental illness found, as well as the attitudes of various groups toward mental illness and psychiatry, the types of psychiatric treatment they obtain, and their clinical response to various treatment methods.

The Syracuse project, initiated by the New York State Mental Hygiene Commission under the direction of Dr. Ernest M. Gruenberg, deals specifically with mental illness in the older age groups. Here, too, a major objective is case finding through the development of methods

for detecting unhospitalized persons with senile psychoses and psychoses with cerebral arteriosclerosis. The project also includes a study of the relationships between the hospitalized and nonhospitalized senile population, according to various social and economic factors. A further step will be the development of clinical and preventive services in the community to learn what effect adequate services can have on reducing the incidence of mental illness among the older residents.

The Phoenix Mental Health Center is conducting a fourth research program of interest. This center is a field research station of the National Institute of Mental Health, established to study the mental health needs of a community and the feasibility and effectiveness of various ways of meeting those needs. To date the project has not involved systematic case finding, but one of the studies conducted at Phoenix has important implications for the development of more adequate case-finding techniques. This was a survey, conducted by the Survey Research Center of the University of Michigan, of public awareness of the mental health aspect of such problems as anxiety about a nervous breakdown, extreme conflict in marriage, and habitual stealing in a child. The survey tried to ascertain what people thought they would do about using the available resources for aid in dealing with such problems.

Interviews with 500 adults, 100 each in five widely varying areas of the city, revealed that many people seemed wholly unaware of the importance of personality development relative to the problems discussed. A great many saw simple circumstances—such things as worry about financial insecurity, the fast pace of life, or family crises—as a sufficient cause for anxiety about a nervous breakdown. Others saw the problem as a lack of will power in the individual. Individuals with such conceptions of causation were likely to see self-help as the only way to handle the problem. Those who mentioned attributes of personality as the primary cause or an aspect of the cause of anxiety about a nervous breakdown were much more likely to report that they would seek professional aid if faced with such a problem.

It was also found, as in several other studies of public opinion on mental health problems,

that more people would seek aid from members of the clergy than from any other group. This study, then, emphasizes some of the reasons why, unless all community resources are mobilized, it is so difficult to detect all cases of mental disorder in a community. Misconceptions about the cause of adjustment problems which apparently prevent many people from seeking available help, coupled with reluctance to admit the existence of problems to which blame attaches, make detection of minor or even relatively severe mental disorders difficult unless there is direct access to the individuals in question.

These and other current research activities, such as that being carried out by Dr. Erich Lindemann and his associates at the Wellesley Human Relations Service, will undoubtedly give us a great deal of valuable information related to the epidemiology of mental disorders in the population. Meanwhile, suggestions for further research are in order. These are of two types, additional community surveys and more intensive follow-up studies of mental hospital patients during and after hospitalization.

Additional community surveys are needed, and needed urgently. Even though we still do not have practical techniques for determining the number of mentally ill, treated and untreated, we need and can obtain some very important data. One type of information concerns the people in the community who are now obtaining various kinds of psychiatric aid. In communities with better-developed services, we can assume that a large proportion of the more seriously ill will be under psychiatric care and, therefore, more accessible to epidemiological study. From this group we can learn a great deal, in spite of the fact that it will not include all of the mentally ill. It is, at least, a starting point.

A community could establish a central clearinghouse of patients, including all residents of public and private mental hospitals, psychiatric wards of general hospitals, and outpatient mental health clinics. This could cover such factors as residence, age, sex, color, marital status, nationality, source of referral, diagnosis, appropriate socioeconomic data, a family roster, and pertinent familial data.

Such a file could be a mine of information, serving not only in basic epidemiological research but also in the planning and development of community mental health projects. For example, the community might be subdivided according to relative rates of usage for various psychiatric services and types of disorders treated. It would be possible to map out the differential distribution of hospitalized disorders, as opposed to those seen in clinics and by private psychiatrists, according to age, race, sex, and residence. It might be possible to detect sociological factors that, within a given area, may differentiate the hospitalized mentally ill from the patients who require only out-patient clinic or office care.

If adequate personnel could be obtained to implement them, special studies could be made to investigate differences in income, occupation, education levels, and attitudes toward mental illness. What are the differences in pattern of family organization and the kinds of emotional problems that these families encounter? What differentiates the families of individuals who use psychiatric facilities from other families in similar areas who do not use them? Are the members of these other families free of serious mental and emotional difficulties or do they have these disorders but handle them in a different manner? What factors influence early submission to treatment, and how is early treatment related to the course of disease and results of treatment? It would also be useful to know something about mortality and morbidity rates from acute and chronic illnesses other than mental illness in families with mentally ill members. From this we might learn whether families of the mentally ill may be a group more vulnerable to health hazards than a control group of families.

Such intensive community studies could have special value because, even if they do not cover all mentally ill persons, they can bring together for a specific population group data on many aspects of mental disorders and related factors which now must be derived from scattered studies on diverse population groups.

More data on mental hospital patients are also urgently needed, especially follow-up information. A major need is in connection with the evaluation of therapy. The concept of the men-

tal hospital merely as a place of custody is no longer acceptable. To make these hospitals effective in their modern role, we must learn more about the patient, what happens to him in the hospital, and what happens upon his return to the community.

We should obtain facts that will enable us to follow groups of patients through their hospitalization and after. For example, of patients admitted in a given year, what proportion remain in the hospital, are on trial visit, discharged, or dead after 1, 2, or 3 years following admission? How are these discharge and death rates related to diagnosis, age on admission, therapy, and other relevant factors?

On a nation-wide basis, we have only the crudest data about discharged patients. We need information on diagnosis, sex, duration of illness, age on admission, types and duration of therapy, duration of stay in the hospital, and condition on discharge. These facts should be analyzed on a life-table basis and by other appropriate statistical methods.

As to patients who have been discharged, how many relapse and how soon? How are relapse rates related to diagnosis, age on admission, length of hospitalization, therapy? Furthermore, we should like to know what social and environmental factors encountered by discharged patients are related to relapse or successful readjustment. Follow-up studies of patients discharged from tuberculosis sanatoria have proved very profitable in our understanding of that disease (11, 12). There is no reason to suppose that such studies would be less valuable in the study of mental illness. If really accurate data are obtained on discharged mental patients, it may be possible to work out "discharge prediction" techniques, weighting significant factors in the patient's life history, diagnosis, clinical course in hospital, degree of improvement, and expected family and community environment. Furthermore, better understanding of relapse factors would greatly aid the development of rehabilitation programs for patients, while they are still in the hospital and later when they have returned to the community.

Some highly encouraging steps taken recently should give us much better hospital data. The National Institute of Mental Health now

takes an annual census of patients in mental hospitals. This work was formerly done by the Bureau of the Census. It has long been recognized that the facts obtained through this census should be expanded to include additional important data. In February 1951, representatives of 11 State hospital systems met in Washington to discuss how better and more useful material could be obtained. These State systems, caring for 55 percent of hospitalized mental patients in the United States, decided to establish a model reporting area which would furnish comparable data on patients under their care. It is anticipated that, as the usefulness of improved reporting becomes apparent, other States will want to improve their reporting and methods of analyzing data to the point where they, too, will be able to enter the model area. It will be several years before the results of this effort will bear fruit but, eventually, it should give us a useful body of raw material for profitable research. In addition, these facts should prove highly useful to hospital administrators in developing and evaluating their programs.

Summary

Our basic knowledge of the distribution of mental illness in the population has distinct limitations. But this is understandable. It is only recently that there has been widespread acceptance of mental health as a sphere of public health and of the fact that an attack on mental illness must reach beyond more serious hospitalized cases to those persons in the community with psychoneuroses and behavior disorders that cause untold suffering and economic loss. Because of the complexity of the problem, effective research on the community aspects of mental illness must be interdisciplinary, combining the skills and knowledge of the psychiatrist, psychologist, social scientist, public health physician and nurse, psychiatric social worker, epidemiologist, and statistician. The fact that at least five projects are currently going on in which a team approach is being used is more than encouraging. We can be sure that progress is being made. Not only should the

projects give us better methods for counting cases; they should also, through their findings, show the way to better service and education programs. Thus can the emphasis in psychiatry's function be changed from treatment to prevention—the emphasis in its location, from the mental hospital to the community.

State of the Nation's Health Services

By Leonard A. Scheele, M. D.

Surgeon General, Public Health Service

As public health administrators, we are increasingly aware of the impact of the Nation's mobilization effort upon our own jobs. We must be alert to the possibility of enemy attack—hence we must devote time and energy to the planning and development of emergency health and medical services for civil defense. Younger members of public health staffs are being drawn into military service. We are called upon to release at least a small portion of our personnel to international health programs. At the same time, the impact of military and industrial expansion for defense is adding to our problems of civilian health. The needed build-up of community health and hospital facilities may be delayed by shortages of materials, supplies, and personnel.

Our health agencies—Federal, State, and local—are struggling with all these problems in an inflationary period. While costs are rising, we are having to operate on somewhat static budgets. In most cases, increases have been slight. No one has yet found a way to make 50 cents do a dollar's worth of work. Even to hold the line at our present level of services, health programs must have budget increases commensurate with increased costs. And to meet the new responsibilities which face all of us, we must have even larger increases in funds.

Our official health agencies are not in a good competitive position to recruit and hold the qualified personnel we require. In the light of the changing economic situation, adequacy of pay and attractive conditions of employment are of paramount importance. The authorization of salary increases is not

enough; appropriations must be made to pay for these increases so that the scope of services will not have to be curtailed in order to meet the necessary higher rates.

Maximum utilization of employees' skills by appropriate placement, training, up-grading, and constructive supervision is a must during the coming year. The increased use of administrative, technical, and sub-professional personnel for tasks that do not require full professional training is one means of meeting the shortages. More effective personnel management alone will not meet the basic need for a real increase in the supply of trained persons. However, it should at least free professional staffs for tasks which only they can perform.

Another dilemma of the health agencies is that graduates from basic professional schools do not come to us prepared for public health

By law, the Surgeon General is required to convene annually "a conference of the health authorities of the several States." The fiftieth conference met in Washington the last week of November 1951. In attendance were the State and Territorial health officers and the State mental health and hospital survey and construction authorities.

An important purpose of the annual conference is to permit the State health authorities to be brought up to date on important national developments in the public health fields. Two general sessions—sponsored jointly by the Public Health Service and the Children's Bureau—were devoted to this purpose.

The fiftieth conference heard from Dr. Scheele on the state of the Nation's health services, and from Mr. Staats on the dollars and cents of health. Dr. Eliot spoke of the children, Mr. Ewing of the aged. Drs. Jones and Potts considered the heart, Dr. Knutson the teeth. The impact of defense mobilization was considered by Dr. Mountain, Mr. Pond, and Miss Arnold. And the implications of malaria infections among servicemen returning from Korea were reviewed by Drs. Myers, Andrews, and Coatsney.

Public Health Reports here presents several of these papers in shortened form, and others as news-type summaries.

work. We are not only unable to attract enough recruits, but the personnel we employ usually must be oriented to their jobs and frequently given specialized training in preventive medicine and public health methods before they are fully useful.

The problems of training cannot be solved by the professional schools alone. All of us—Federal, State,

and local agencies—have a responsibility within our own organizations to develop good training programs if we are to have health manpower with the kinds of skill and experience our programs require.

Partnership and Morale

The Public Health Service and the State and local health departments have a long history of partnership. With the advent of grant-in-aid programs in 1935, we began to create and perfect a kind of teamwork—a mechanism, if you will—that really works. Much more is involved in this relationship than money—much more than the transfer of Federal funds to State treasuries—much more than the increasingly complicated administrative procedures. These business problems plague us all, but as custodians of public funds and public trust, we must accept them.

What is involved is a way of working together as technical experts for the solution of public health problems which affect the entire population. I am bold to say that the people of the United States would lose more in health protection if the teamwork of national, State, and local agencies—voluntary and official—were disrupted, than if all the Federal health grants were wiped out tomorrow.

And yet there comes the suggestion that the States can go it alone in public health work. That there is no need—or less need—for Federal assistance and cooperation; that there is too much Federal action. The complaints are familiar to all of you.

The objective of the Public Health Service is, and will be, to increase the self-reliance of State and local health agencies. If our policies and procedures seem to disregard that objective, if any member of our staff forgets it, the channels are wide open to bring the facts to our attention.

I cannot, however, visualize our Federal, State, and local health agencies getting their respective jobs done effectively without each other's help. It is to the advantage of all of us—and more important, to the health of the American people—that

we maintain our working relationships.

The winds of conflicting opinion are high these days. Differences may be political or professional or both. If public health people are to discharge the public trust invested in them, they cannot afford to bend before every partisan blast.

Public health has won and held its place in our democratic society by its single-minded devotion to the public interest. I regret to say that some of us occasionally yield to the temptations put forth by various groups, in the hope of winning a temporary or a personal advantage. In so doing, they are destroying the cause for which they and all the rest of us are working.

This is the time of all times when each and every one of us must stand firm for the principles and concepts of public health. More than ever, public health workers and the practitioners of medicine can and should work side by side with common understanding and purpose. Let it be said of us that “after the whirlwind, the still small voice”—the public interest—has informed and guided our every action.

Adjusting Programs to Needs

The Nation's public health organization is in a period of adjusting programs to needs. Everything seems to be coming at health agencies at once. With one hand, we try to keep up with scientific and technological advances in our traditional programs. With the other, we try to cope with the new problems: health of the aging, chronic disease control, rehabilitation, mental health services, and so on. We are in process of engrafting more individualized services into a program that has been broadly impersonal.

In some areas, we have developed a complementary relationship with the medical profession which makes it possible for the health agency and the private practitioner to carry out their respective functions with little difficulty or friction. If a case of diphtheria occurs, for example, the physician reports it to the health department; the department takes a culture for diagnosis and if need be provides at public expense the

antitoxin for the patient and toxoid for susceptible contacts. The physician proceeds to treat his patient, and the health department follows up with another culture before the patient is discharged. In the meantime, the department will have conducted an epidemiological investigation and taken action to prevent spread of the disease. Everyone has known what to do, what to expect, and what the objectives are.

At the present time, we do not have as fully developed a complementary relationship with the medical profession in our programs for heart disease control, cancer, and mental illness. Yet such a relationship can be developed—and should be.

Emergency Resources

The Public Health Service has been working closely with the Health Resources Advisory Committee of the Office of Defense Mobilization—commonly known as the Rusk Committee. We not only have assigned personnel to the committee on a full-time basis, but have undertaken several studies for them to provide the factual bases of planning and programming.

One such study of vacancies in State and local health agencies has pointed up the fact that the numbers of vacant budgeted positions do not provide a full expression of total needs. On the basis of recommended minimum staffing requirements for local health departments operating a limited program, it appears that there are wide discrepancies between vacant positions and actual needs. In our regions II, V, and IX, for example, the number of additional public health physicians needed is 3½ times greater than the number of vacancies. If all local health departments were brought up to the minimum standard of 1 public health nurse per 5,000 population, more than 10 times as many additional nurses would be needed as are indicated by vacancies. The corresponding figure for sanitation personnel is 3½.

The future of public health in a long-term mobilization period de-

pendes very heavily on our estimates of need for personnel. If we base such estimates on a narrow view of our responsibilities, our chances of maintaining adequate health manpower will be lessened. The Public Health Service has recommended to the Rusk Committee that some detailed field studies be made for the purpose of re-evaluating the standards now generally in use. Such studies should provide data upon which to base realistic estimates of need.

The Rusk Committee has recently appointed a committee to coordinate the National Blood Program—another field in which health agencies are vitally concerned. The committee is headed by Dr. G. D. Cummings, director, division of laboratories, Michigan Department of Health, and includes representatives of the Department of Defense, the American National Red Cross, the Public Health Service, and the Federal Civil Defense Administration. A small group of specialists in this field will advise on the procurement, allocation, and use of blood and blood derivatives, basic research and clinical testing of blood derivatives and extenders, establishment of standards, storage, reserve, and transportation.

The research and development program now operating in and through the National Institutes of Health will help to solve some of the basic problems which hamper the preservation of blood and the production of blood extenders. We operate on a very limited budget, however, and there are only a few research teams in the country sufficiently well trained to evaluate the effectiveness of the methods employed to preserve blood. Hence, progress may be slow. An immediate need is for the States to come forward and do their share with the Federal and voluntary agencies in the establishment and maintenance of standards for the Nation's blood banks.

The development of sound medical and public health services which can be called upon with assurance for civil defense is of the utmost importance. Certain requirements of civil defense depend primarily on basic public health functions which

must be developed, improved, and expanded—regardless of whether we avert war, or whether we must meet it head on next week, or in 2 years or 10 years.

Public Health in Civil Defense

An active, well-planned epidemic intelligence service is one of these first requirements. To achieve an adequate epidemic intelligence service, we need a more efficient nation-wide system of morbidity reporting, a network of laboratories to collaborate in microbiological research and detection of infectious agents, and a field service to assist in the practical control of epidemics or outbreaks of unusual diseases.

Special conferences and discussions have been held during the year on the new plan for morbidity reporting. The plan goes into operation on January 1, 1952.

A coordinated regional laboratory and epidemic intelligence service has been developed by the National Institutes of Health and the Bureau of State Services during the year. If the regional laboratory and epidemic intelligence service are to be of maximum use, especially in emergencies, the State health departments and the Public Health Service staffs will have to develop close coordination and effective teamwork. I hope that this program will be functioning at peak efficiency by the close of the current fiscal year.

Civilian Health Requirements

Still another field of major importance is the strengthening of our Nation's health and hospital facilities. The Public Health Service is claimant before the Defense Production Administration for all health supplies and equipment and for construction of all hospitals, excluding military and veterans' facilities. The problem in civilian health requirements of most immediate concern relates to the allocation of controlled materials for the construction of hospitals and health facilities. In the area of health supplies, we are in a somewhat better position at the moment. Under the Controlled Materials Plan, the Defense Production Administration receives requests from all the claimant agencies, on

a quarterly basis, and then proceeds to allocate to them quantities of steel, copper, and aluminum to be used in their respective fields.

The task which confronts the Public Health Service is to determine priorities for the allocation of a limited supply of materials to hundreds of construction projects. Here we turn to the State health and hospital agencies for assistance. We are depending upon you to assist the project sponsors in preparing their requests and to furnish them consultation on the conservation of critical materials. Then, we would like to have you collect and analyze data concerning the requests for construction, appraise the projects with reference to their potential contribution to health and medical care needs in relation to the defense effort, and make recommendations to the Service regarding the essentiality of the projects. Only on the basis of such first-hand information and judgment can the Public Health Service carry out an equitable determination of priorities for scarce materials.

Facilities and Services

Perhaps no other recent event is of such immediate interest to health agencies as the approval, on September 1, of the Defense Housing and Community Facilities and Services Act of 1951 (P. L. 139, 82d Cong., 1st sess.). The law places additional—but not unfamiliar—responsibilities on the Public Health Service and State health and hospital construction agencies. The provisions which directly concern us are similar to those of the Lanham Act of World War II.

In the administration of this program, the Public Health Service will turn to the State agencies as we have in the past. We expect to use the services of the State sanitary engineers to the fullest extent possible. When and if appropriations are made under Public Law No. 139 for hospital construction, we shall turn to the State health and hospital agencies. Funds are available only for water and sewage treatment plants and interceptor sewers within the range of operation of the Public Health Service program.

Mobilization requires a tremendous output of the Nation's physical, mental, and spiritual energies. We must use more fully and more efficiently the capacities of our older citizens and of the handicapped. The development of our chronic disease control programs, occupational health, and rehabilitation services is of the utmost importance. As new programs related to the health and greater productivity of the Nation come into being, our Federal, State,

and local health agencies must be at the forefront—ready and willing to take on their share of new responsibilities in a positive way.

America's enormous material resources are but the product of her human resources. The martialing of the Nation's power against the threat of aggression is dependent—utterly dependent—upon the physical, mental, and spiritual vigor of the people. The Nation's health services—official and voluntary—were

created and are maintained to contribute to the vigor of each individual. A narrower view of our goal and our mission will only lead to failure in the hour of crisis. Our long-standing alliance for the health of the American people leads me to believe that our organizations together will take the leadership in the efficient operation of programs that seem difficult to groups less skilled in the ways of public health and teamwork.

Dollars and Cents of Health

Health and Hospital Programs In the Federal Budget

By Elmer B. Staats

Assistant Director, Bureau of the Budget

In the field of public health the three levels of Government—local, State, and Federal—are engaged in an extensive cooperative enterprise, providing health services which contribute toward the common goal of better health for the individual, the family, and the community.

In the scale of values of the American people, health is recognized as a basic resource, essential for immediate military security as well as for our longer-term economic growth, social development, and individual well-being. Since the fiscal year 1946, expenditures by the United States Public Health Service alone have expanded from a level of \$118 million to an estimated level above \$300 million for the present fiscal year of 1952. This rapid increase has occurred in a period when other imperative needs are straining the fiscal resources of the Nation.

Outlines of Federal Budget

Before discussing with you the current status of Federal hospital and health programs, I should like to indicate briefly the broad outlines of the Federal budget. Of expenditures totaling approximately \$70 billion in this fiscal year, about \$60 billion, or 85 percent, are required solely to meet the needs of our national security programs, the interest on the national debt, and

commitments for veterans' services and benefits. This means that for the current fiscal year, only about \$10 billion is included to finance most of the domestic or civilian activities of the Government, and even within this segment of the budget, less than two-thirds is subject to reallocation or reduction through the normal budgetary process. Much of it is committed for meeting such relatively fixed and predetermined obligations of the Government as the

contributions to retirement funds for railroad workers and Government employees, the recurrent postal deficit, and subsidies to merchant shipping. This part of the budget provides also for practically all the \$2.7 billion of grants to State and local governments under existing laws. Moreover, this \$10 billion for civilian domestic programs includes numerous items which have direct and obvious relationships to the defense effort, including defense power projects, internal security, and protection of harbors and ports. Yet, paradoxically enough, this is the area against which the charges of "big Government" are most frequently hurled. This is generally the area where those who would balance the budget usually direct their attention.

Postwar Problems

We emerged from World War II with a relatively large military program and new international responsibilities, both designed to preserve our national security in the uncertain postwar world. We emerged with a debt more than six times greater, costing us more than \$5 billion annually in interest alone. We emerged with 15 million new veterans, many needing hospitalization and eligible for readjustment training and education benefits. These new and enlarged responsibilities created a large new hard core for the Federal budget—four times greater than it had been a decade before.

We emerged also from a period during which our domestic programs had been virtually closed down. Our economy had been expanding, science

and technology had made tremendous strides, and our population had grown, but during these years we had been building up an ever-increasing backlog of needs—needs for more housing, for improved highways, for increased medical research and training, for new natural resource developments, for more adequate measures of social welfare and security.

One of the great problems facing the Federal Government during the postwar years has been the achievement of a balanced domestic program within the limited number of available dollars.

Furthermore, that problem has been immeasurably heightened, not lessened, since the outbreak of the Korean conflict and the immediate steps taken to expand our armed forces and our mobilization base. In July 1950, the President took steps to curtail, defer, or redirect the nondefense programs in the budget by calling upon all executive agencies to defer or curtail public works construction, to reduce credit activities, and to restrict Government purchasing. The Congress also, in the General Appropriation Bill for 1951 several months later, directed the Bureau of the Budget to reduce the appropriations voted in that bill by \$550 million "without impairing the national defense." Under that directive, all Federal programs were carefully screened, particularly those in the construction field where there was particular competition for men, materials, and supplies. The Federal-aid hospital program was one of the programs slowed down.

Again today the outlook is not bright for any material easing of the restrictions applied to domestic programs. The momentum of the defense program authorized during the last two sessions of Congress is only now beginning to exert its full impact on budget expenditures. Since Korea the Congress has authorized appropriations totaling more than \$170 billion. By the end of this fiscal year only some \$100 billion of that total will have been spent. That means that we will enter the fiscal year 1953, next July 1, with billions of dollars of goods on

Total Budget Expenditures

Fiscal Year	Billions
1952 Est.	\$71.6
1951 Est.	47.2
1950	40.1
1949	40.0
1948	33.8
1945	98.7

Based on proposals of the President.

order for which expenditures will be made in 1953 and later. These expenditures, together with those for pay and maintenance of our men in uniform, will cause direct defense and other national security expenditures to rise to a substantially higher level in the fiscal year 1953. Thus, even if we merely maintain our domestic expenditures at the same level in 1953 as in 1952, the total of Federal budget expenditures will exceed \$80 billion. Even after allowing for the higher receipts arising from the Revenue Act of 1951 and a higher level of economic activity in the

months ahead, we face a sizable and sobering deficit for 1953 and perhaps even beyond.

In referring to the limited funds available for civilian or domestic programs in the budget, I do not mean to imply that there is any fixed or arbitrary total available for these programs from year to year. Nothing could be further from the truth. Each individual program must be weighed and compared with a multitude of other programs in terms of its potential importance to the Nation as well as its short-run contribution to defense needs and essen-

tial civilian requirements. In our rapidly expanding defense economy, the Government's jobs of providing postal service, operating the Federal airways, patrolling the borders, or collecting taxes and customs get bigger, not smaller. In other fields, the Government's efforts must be redirected so that housing, the protection of health, and the operation of schools are particularly assured in critical defense areas. The utmost selectivity is required to keep the budget total within reasonable bounds.

Health and Hospitals

I should like now to indicate something of the range and financial importance of Federal activities in your field of special interest.

Taking the budget as a whole—military, veterans, and all the rest—we find that in the current year the Federal Government is spending more than \$1.75 billion on health and hospital programs. That is, more than \$1.75 billion of this year's \$70 billion is for health and hospital purposes. Most of this is for directly operated Federal programs, and particularly for such special groups as veterans and the military services. Veterans, of course, are predominant in these Federal totals.

Although only a rough estimate is available for State and local governments, the Federal total appears to be a substantially greater sum than is spent by all the State and local governments on health and hospital programs, including mental care.

Through its own hospitals and outpatient clinics, the Federal Government provides medical services and hospital care that are available in some measure to more than 25 million people. Included in this eligible group are the 18.5 million war veterans; the 3.5 million officers and enlisted personnel of the Army, Navy, and Air Force, and certain of their dependents; 400,000 American Indians and the Eskimos and other natives of Alaska; some 2 million civilian Federal employees, in the event of injury or illness in line of duty; 100,000 American merchant seamen; 30,000 Coast Guardsmen and their dependents; 50,000 civilians in the Panama Canal Zone; and

nearly 20,000 persons in Federal institutions.

Some of these hospital and medical services are purchased from local and private contractors or from professional people. A much larger proportion of the services is provided, however, by Government personnel in Federal facilities. In fact, the Federal Government operates nearly 20 percent of all the hospital beds in the United States. Through the Veterans Administration, the military departments, the Public Health Service, and the Indian Service, the Federal Government operates in the continental United States more than 500 hospitals with a total capacity of 220,000 beds. In addition, the Armed Forces maintains many hospitals overseas.

Cooperative Health Programs

The Federal Government makes its contribution toward the health work of the States by means of demonstrations, educational programs, technical help, and both pure and applied research, but more largely through financial assistance. This financial assistance takes the form of grants-in-aid to State health authorities; research grants not only to public institutions but also to non-profit private institutions and to individual scientists; and training grants to individuals.

At present, the Federal Government makes numerous grants to State and local governments for various kinds of governmental activities, amounting for all purposes to about \$2.7 billion a year. Public assistance and highways take more than 60 percent of the grants, and the remainder is distributed under 44 separate grant programs. There are 10 separate grant programs directly in the field of health, including not only the hospital survey and construction program, on which Federal expenditures in the current fiscal year may exceed \$150 million, and the general health grants to States, amounting this year to \$14 million, but also five programs directed to specified categories of disease—venereal disease; tuberculosis, heart disease, cancer, and mental illness. Other grants are provided for maternal and child welfare (administered by the Chil-

dren's Bureau), disease and sanitation control in Alaska, and water pollution control. For the current fiscal year, grant expenditures under the 10 health programs are estimated at \$233 million.

Closely related to these health grant programs are selected phases of some other Federal grant programs, such as civil defense contributions of medical supplies and equipment to State and local governments and direct Federal expenditures for procuring and stockpiling additional medical supplies and equipment. Another defense-related grant program in the health field was authorized at the last session of Congress for the provision of community facilities and services in critical defense housing areas. An appropriation of \$4 million was voted to cover, during the fiscal year 1952, the functions and duties of the Public Health Service with respect to health, refuse disposal, sewage treatment, and water purification, as well as other functions of the Federal Security Agency in these critical defense areas.

The vocational rehabilitation, school lunch, and public assistance grant programs also have health and medical aspects, but I have not included these programs among health grants.

The Role of Federal Grants

Without entering into an evaluation of each of the 10 health grants, several general observations may be made about Federal grants-in-aid generally which might point the way toward basic improvements of Federal policy for the health grants.

The role of the grant-in-aid in our governmental system is often misunderstood. The grant is often described as an instrument of centralization. Actually, it is a partnership arrangement. In fields where it is practicable, the Federal grant stands midway between direct Federal operation with complete Federal financing of a service at one extreme, and complete State (or State and local) financing and operation at the other. As a cooperative device, the grant helps to preserve the vitality of our Federal system of Government.

Inequalities are bound to occur

between the needs of the people of a State or local community for governmental services, on the one hand, and the ability of that area to finance those services from locally available taxes, on the other. Some States can support a high standard of public service with a low tax rate; others have to skimp on services despite high tax rates.

The Federal grant-in-aid helps to reduce somewhat these interstate inequalities. The basis and the justification for a Federal grant is that there is a national interest in the services being financed. In contrast, a complete separation and sharp division of tax sources and functions between the Federal and the State governments, such as is occasionally proposed, would constitute, in effect, a denial of any national interest in the services to be rendered by the States. In the field of health and in such other fields as highways, public assistance, and education, the existence of that national interest cannot be denied. The need, therefore, is for policy in the use of grants-in-aid which will give proper recognition to the appropriate contributions of the Federal and the State levels of government.

To serve national objectives effectively at reasonable cost, each grant needs to be so distributed that the share for each State will reflect its need for the particular service and also its capacity to finance the minimum level of service from its own taxable resources.

At the same time that the Federal grant provides national assistance in financing a service, it leaves to State or local governments actual administration of the program. Thus the State has—or should have—a substantial measure of discretion in adapting the program to local needs and customs. The States do, of course, operate within a framework of broad national policies for the grant program. But within these policies the States decide how far to go with a particular program, and they determine the day-to-day content and quality of the operations.

Grant-in-aid programs have sometimes been too narrowly defined; that is, their content and direction in some cases have been too precisely

and specifically set forth in Federal law or regulation. When federally aided programs are defined too narrowly, the State may have no direct incentive to economy and efficiency in the use of Federal money, since any savings it makes on the aided program ordinarily are not available for other use by the State.

This problem of overly narrow grant categories is particularly present in the field of health. It creates difficulties in budgeting, but even more important, it may hamper flexible and efficient administration by State and local officials. At the outset, a narrow definition of purpose may be adopted because a particular disease is the subject of special public concern or because of a widespread belief that a concerted, dramatic, Nation-wide effort on a co-operative basis may conquer the disease. But laws and programs tend to stay on the books and continue in operation even after needs have changed. The use of broad categories instead of narrow, selective ones permits the redirection of money and effort as needs change. Particularly, it permits individual States and communities to adjust their current programs to new conditions, including the possibility that a successful attack on a particular disease may actually reduce the need for the specific categorical grant in varying degrees in different areas.

New health problems created by the defense effort especially point up the desirability of flexible budgeting and programming for health services. It may be that limitations contained in some Federal grant statutes are interfering with that reorientation of activities which will assure highest priority to the needs of the defense effort.

These considerations raise the question whether it might be timely to undertake a complete and systematic review of all the Federal grants for promoting health, reconsidering the scope or subject matter of each program, and the conditions attached to the grant. Possibly the grant-in-aid system for health would be more effective and economical if certain basic changes were made—for example, (1) if existing piecemeal programs were consolidated

into broader programs, (2) if the grants could be somewhat more definitely related to the fiscal resources of the States, as well as to the States' needs for the services, and (3) if the minimum service standards or objectives could somehow be expressed in terms of results achieved rather than in terms of dollars spent.

In such a review, the health grants might well be re-evaluated in terms of their specific objectives. At the same time, they should be appraised one against another and each against all the programs and commitments of the Federal Government, with the aim of determining whether the amounts devoted by the Federal Government to the several grant programs are at least roughly proportionate to the national interest in each of these programs. Although we endeavor in the normal processes of budgetary review to promote a better balance among programs, a thoroughgoing realignment would require legislative action.

Finally, it might be productive if the administrative arrangements for the Federal grants were reviewed with the objective of attaining more uniformity and simplicity, more adequate safeguards for the Federal Government, and more definite State-local responsibility for operations and for adaptations of each program to special situations. At present, some Federal laws in the general field of grants-in-aid permit or even require an unnecessary amount of Federal interference in State operations, while others are so restrictive that Federal officials have no discretion. I have not examined the health grants closely enough to know whether they now exhibit such variations. But, in general, it can be suggested as a good principle that the Federal administrator should have enough authority to make sure that the national interests are protected, but not so much authority that coercion is substituted for cooperation.

Uniformity among Federal grant programs is by no means an end in itself, since the purposes of the grants and the conditions under which they must apply are themselves varied. But sometimes there are procedural variations between

Federal Budget for Social Security, Welfare, and Health, 1952

Where the Money Will Go in 1952

Total Expenditures SOCIAL SECURITY, WELFARE, AND HEALTH

Fiscal Year	Millions	% of Budget
1952 Est.	\$2,625	3.7
1951 Est.	2,520	5.3
1950	2,213	5.5
1949	1,907	4.8
1948	1,869	5.5
1945	1,046	1.0

PERCENT OF 1952 BUDGET

Based on proposals of the President.

laws which entail extra cost and introduce complexities without serving major purposes. If such differences exist in the health grants, they might well be identified and corrected as one result of a comprehensive review.

The kind of review I am suggesting would look toward the long-run improvement of the entire Federal program in the field of health grants. Its principal results, therefore, would presumably be reflected in legislation and administration, but the conclusions of any such study would have a direct bearing also upon the

programing and budgeting of health activities, both for the long run and from year to year.

Budgetary Outlook

I indicated earlier that I would try to comment on the implications of our present budgetary outlook for Federal health and hospital programs in 1953. The general objective which guides our current review of budget requests for 1953 is that the over-all size of the budget—which means the aggregate use of goods and services by the Government—shall be held to the minimum

level that will assure adequate national defense, an expanding volume of essential production, and a strong and stable economic system for the Nation. The detailed recommendations in the 1953 budget, to be transmitted to Congress in January 1952, will have to be grounded on this basic purpose.

To make the general policy effective, certain specific rules have been spelled out. For example, new civil public works construction projects will be recommended only if they contribute to meeting defense needs. Similarly, other new activities will be restricted to those which contribute directly to defense or toward sustaining a continued defense economy and military effort. Moreover, all existing programs are being re-examined in the light of the unprecedentedly heavy peacetime demands of national defense and international security. The broad implications for public health programs may be summarized in this way:

First, the expansion of basic health programs of the Federal Government will be limited to those contributing directly to national defense.

Second, the States should continue their efforts to reorient health programs to needs arising from the emergency. In our governmental system, public health is basically a State and local responsibility, and it is through the State and local health services, whether assisted by Federal funds or not, that the Nation will have to meet the challenges created by the defense emergency.

Third, it seems inevitable that the continued growth and development of health services that might have been possible under more favorable conditions will be slowed down considerably. This is one of the many serious losses that we have to sustain in these troubled times.

Need for Program Review

The last decade has witnessed a great expansion not only in the direct Federal programs serving specific groups, but also in the cooperative Federal-State programs in the field of health. At this time, we need to re-evaluate the whole range of

these governmental health programs, to be sure that they are the right programs for today's needs, that they are economically and effectively administered, that they add up to a balanced program in the local communities and States and for the Nation, and that our health services as a whole are in proper proportion to other essential services. Such a re-evaluation is difficult, but it is nec-

essary. Under our system of government, all public programs quite properly must undergo constant and complete reconsideration. It is important that this reappraisal be based on informed judgment as to needs, objectives, and available resources.

Above all, whether as budget makers, professional workers in the field of health, public administrators and legislators, or just plain citizens, all

of us have an interest and an obligation in this matter. Together we must see to it that the preservation and promotion of the people's health takes its proper place among our public objectives in this difficult period—this period when the attention and energies of the Nation are primarily devoted to meeting the urgent and unavoidable demands of national defense.

The Children

New Horizons for Child Health

By Martha M. Eliot, M. D.

Chief, Children's Bureau

The States have every right to be satisfied with the way the infant mortality rate for the Nation has been reduced from 100 deaths per 1,000 live births in 1915 to 29 in 1950. To some nations around the world where infant mortality rates are 10 times as high, this is a phenomenal record. But those of us who are close to the situation in this country know how much more we could do to reduce even this figure of 29. There are areas in our country where the rate is twice the national average. In 1949, this rate was 63 percent higher for nonwhite than for white babies. Babies are dying needlessly in many places, particularly in the Southwest and Southeast.

To save more babies, we will have to work on many fronts, not all of them strictly in the field of public health. The health officer and his staff of nurses and sanitarians will need the help of such special health and allied workers as health education specialists who can help in community planning, nutritionists who can advise on food for both mother and child, medical social workers and child welfare workers who are especially skilled in helping families with their social problems, teachers who can work health education into their courses wherever appropriate, economists and social scientists to interpret the problems related to income and cultural patterns.

Causes of death associated with premature births are still responsible for a third of the infant deaths

occurring in the first year of life. In the last 20 years we have cut nearly in half the proportion of all reported deliveries ending in fetal death, but even now the rate of fetal deaths remains at about 2 percent of deliveries.

Much more research is needed if we are to get at the causes of premature birth and fetal death and, therefore, to be better able to prevent them. We already know from studies that mothers who have good diets during pregnancy have fewer premature deliveries than mothers who have poor diets.

It is good to know that in 1950 only 7 mothers died in childbirth for every 10,000 live births, compared with 58 in 1939. But we cannot take pride in the fact that the rate for nonwhite mothers is more

than three times what it is for white mothers. Nor is mere survival all that we want for mothers. Every mother should come through her maternity experience with abounding health, both physical and emotional.

The great reduction, since the last war, in the number of days that mothers stay in hospitals raises some new problems. What happens to mothers who go back to their households 3 or 4 days after delivery? This is something that needs study. Should we not examine our maternity facilities and see if they are as simple and flexible as is compatible with maternity care of high quality?

Much needs to be done, too, to improve standards of care in maternity and children's hospitals. Hospital practices should be examined to make sure they do not unnecessarily create emotional problems but do contribute positively to the emotional as well as the physical health of both mother and child. The growing interest in rooming-in arrangements is one sign of an improved attitude toward the mother's and the infant's psychological needs.

For many years one of the major tools of the maternal and child health program has been the child health conference. Its original purpose was, of course, to reduce infant mortality. Today, the work of the child health conference is directed more toward helping parents with normal everyday problems in the growth and development of their children. It is time we should ask whether the child health conference is still an effective tool for this purpose. Does it need revamping? What staffing patterns are desirable today? These are things that need study.

In recent years much progress has been made in evaluating health services for the child of school age, both the services within the school itself and those provided by the community. The new statement sponsored jointly by the National Council of Chief State School Officers and the Association of State and Territorial Health Officers on "Responsibilities of State Departments of Education and Health for School Health Services" will certainly help to focus attention on how these services can go forward. The Federal Security Agency Committee on Health Services for School-Age Children, on which the Public Health Service, the Office of Education, and the Children's Bureau are represented, is about to issue a publication called "Better Health for School-Age Children." It includes practical suggestions on how communities can figure out for themselves which things most need doing.

Health Services for Children

As communities give more careful and inclusive consideration to the problems of providing day-care centers for children of working mothers, foster family care, adoption services, institutional care, and services for juvenile delinquents, they are sure to find that health services and medical care are essential to well-rounded programs in these fields. It is my understanding that State and local health agencies are cooperating increasingly with State and local education and welfare agencies, with State youth authorities, and with law enforcement agencies, such as the juvenile courts, on the physical and mental health aspects of their programs. But only a beginning has been made. In many institutions for children, including training schools for delinquent boys or girls, health services are inadequately provided. In this connection, may I remind you that funds for maternal and child health and crippled children's services may be used to assist other State and local agencies in developing adequate health and medical services for children and young people coming within their scope.

Undoubtedly the Mid-Century

White House Conference on Children and Youth did much to stimulate widespread consideration of the multi-professional approach to the needs of children and increased cooperation among public and voluntary agencies. In many States committees on children and youth will continue to provide the opportunity for such joint planning. State and local health agencies can do much to stimulate the work of these committees.

Handicapped Children

With respect to the State programs for care of crippled children, I believe that you have reason to be gratified by recent developments. The improvements are of many kinds. All together, 215,000 children were cared for in 1950, an increase of 18 percent over the number the year before. Although children with orthopedic conditions still make up a large proportion of the total number treated under the State programs, it is heartening to see the way State agencies are broadening their programs beyond orthopedic services to include care for many different kinds of handicapping conditions.

Epileptic children are among the most recent to be included in crippled children's programs. Services for these children offer a very good example of the importance of close teamwork between health services and the community. To develop better community understanding and to train more workers in this field, two States are assisting medical schools in providing courses for physicians, nurses, social workers, and others. As workers are trained, services for epileptic children can expand.

Some States are doing fine things for children with impaired hearing. So much can be done for these children now that was never possible before. Already a few States are assisting universities to train more audiologists.

A vast majority of the 175,000 children with cerebral palsy can benefit enormously from skilled assistance, but so far as anyone can tell only a fraction are now getting it. About a dozen State agencies

have developed comprehensive programs for these children, usually geographically limited, but they include physician's care; physical, occupational, and speech therapy; medical social services; public health nursing; and special teaching arrangements. Comprehensive programs such as these are needed in many other States.

At present, 26 State health departments and crippled children's agencies have programs for the care of children with rheumatic fever. The fact that so many States have undertaken to demonstrate care shows how wide the interest in this is. As you know, it is now the policy of the Children's Bureau gradually to withdraw from these programs the funds that have been especially reserved. However, it is hoped that States having these projects will carry them on and expand them by seeking State funds as well as by using some of their regular Federal funds.

Regional Programs

New methods of diagnosis and treatment are being developed on all sides. One such development is in the field of congenital heart disease. Not every State has the highly trained surgical and pediatric specialists needed to give care to children with this condition. So that States without facilities can refer their children to an outstanding center nearby, a regional program has been developed. Connecticut has set up the machinery for the first of such regional programs. California will probably be next. When the nationwide planning is complete there should be five or six such regional programs strategically placed so that children with congenital heart disease in every State in the Union may have access to specialized diagnosis and surgery.

This device of pooling resources on a regional basis has large promise, too, for the care of children with other types of handicaps which call for highly skilled treatment, such as cleft lip and palate. It also has great significance for other types of regional planning: for example, the establishment and use of education and training programs; the sharing of special consultants; and the use

of special diagnostic and treatment facilities by two or three States.

Cutting across all phases of both the maternal and child health and crippled children's programs is the question of recruiting and training more and better personnel. This, I believe, is the number one problem in advancing child health work.

We need a long-range plan of work with universities and colleges, with schools of medicine, nursing, and social work, to recruit personnel to enter the child health field. Joint planning between undergraduate and graduate schools is necessary. Undergraduate curriculums should be developed to attract new students to prepare themselves for graduate work. Economic, racial, and sex barriers will have to be broken down. Pay and working conditions will have to be made more attractive. More funds will have to be made available to enable educational institutions to strengthen their facul-

ties with competent teachers in maternal and child health and in the related fields.

Professional schools are realizing the need for including instruction on child growth and development to give all types of workers with children the newer concepts of physical, mental, and social health. New recruits to the field of child health must be as sensitive to the emotional needs of children as they are to their physical management.

Second only to a satisfactory program of recruitment and training is the research necessary to obtain new facts on which new or modified programs can be based, and to evaluate the progress, quality, effectiveness, and cost of on-going work. Increasingly, State agencies are becoming interested in studying and evaluating their own programs. Within its resources the Children's Bureau stands ready to assist and to advise

on ways and means of making such evaluations.

The strength of the Children's Bureau and its greatest value lie in the fact that our concern is with all of child life and that we work across the board with the States on all the health and welfare aspects of this business of growing up. As long as I am with the Bureau I shall no doubt keep on reminding you that you can't split up a child; that children with health problems also have social and emotional problems; that children who are neglected, delinquent, and dependent also have health problems. I shall probably keep hammering away, too, on the old theme that all professions working with children should know about the way normal children grow if they are to do a good job either with normal or sick children. I shall urge constantly close teamwork between all professions working with children.

Older Citizens

Aging—Weakness or Strength?

By Oscar R. Ewing

Federal Security Administrator

The changing age distribution of our population is emerging as an overriding challenge of our time. It is a challenge to all of the social sciences; certainly to public health.

By and large, the later years do not fulfill the promises that we traditionally attach to them. In all too many instances, instead of bringing fulfillment of hopes they are barren and empty. In a nation still fundamentally oriented to youth, older people become bewildered, confused, and insecure.

Even if the world were at peace with itself, this would present a major challenge. Against the backdrop of the greatest test that this country has ever had to face, it becomes a matter of deep national concern.

The United States is stronger today than ever before in its history, but the demands upon it have increased accordingly. How much stronger we shall have to become to stand up to the trials ahead no man can say.

This much, however, seems clear: Not one of us can take an easy breath until every segment of our society is in a position to put forth its full

quota of productive effort—and that includes the older members of our society.

Whether our older citizens become a national asset in the trial of strength that we are now in, or whether they become a serious drain on our economy could well make the difference between success and failure in the times ahead.

I should like to suggest that one of the most important things that we have to do at this point is to re-examine our attitudes, as a people, toward our older citizens.

We have fallen into the habit of judging the worth of people by the number of birthdays they have had. Ultimately, I suppose, the calendar rules our lives. But it can play tricks on us, if we let it.

Can Play Tricks

This habit of looking at a person's age instead of at the person is, it seems to me, but part of a larger tendency which is somehow characteristic of these days and times—that is, the tendency to throw everything into the discard which is old, simply by reason of its age, and to admire and respect that which is

new, simply by reason of its newness.

That applies not only to material things; unfortunately, it applies to some extent also to people.

I venture to say that the discarding of people who for one reason or another have gone out of "style" represents today our greatest single national waste; that a reversal of this attitude would point the way toward development of our greatest single idle asset.

Revision of Attitude Needed

We don't have to wait for a big formal program to revise our attitudes toward the phenomenon of aging. We can start doing something about it now.

Let me be a little more specific.

A good many people go into the discard every year, not through their own choice but through forced retirement—in many instances, years before their productive capacities have been exhausted or even seriously impaired.

They are shunted off by society into the valley of lost men—not because they have nothing more to contribute to society and to their own happiness but simply because the earth has made so many revolutions around the sun since they were born.

This alone constitutes a serious loss to society.

A companion problem is that represented by the uncounted numbers of perfectly capable men and women who, for one reason or another, find it necessary to seek new employment relatively late in the period of life that we call the working years—when they are 45, say, or 50. Many companies will not even consider the applications of persons 45 or over. But even if the employer doesn't have a set rule about it, age is a handicap. Regardless of the applicant's real abilities, his judgment, his experience, his emotional stability, his wisdom even, he is under a cloud—simply by reason of having lived so long.

In addition to these very considerable groups, there are the thousands upon thousands of workers—or would-be workers—whose capacities have clearly been changed by

age but who, given the right encouragement, the right guidance, the right tasks, the right working environment could be productive and useful members of society but who, in the absence of these things, slip little by little into the discard.

Actually, in a good many jobs older workers not only perform as well as younger, less experienced workers—they perform better. . . .

Finally, there are the ever-increasing numbers of older people who, through apparent or real disability, are forced to eke out the remainder of their days in mental institutions, hospitals, and nursing homes—burdens to themselves and burdens to society. There is a growing realization, and some significant evidence, that a good many of these unfortunate people can be cared for better—even, perhaps, less expensively—in their own homes, in foster homes, under the family-care plan, or in residence clubs.

The large components of the older population that I have cited represent but a few examples of the problem of aging. I recognize, too, that they are vastly oversimplified examples.

I don't suppose we have ever been confronted with a problem that has crossed so many professional boundary lines or that has so deeply involved our social and economic institutions. What the older members of our population do with their time is not a matter of concern to them alone; it is a matter of concern to all society.

It seems to me that the key to this whole situation is simply this: Let us make up our minds to go to work on this problem with what we now know and with the resources that we now have. In other words, let's start from where we are.

We need not wait until we have all the answers. While there is much that we do not yet know, many things about the phenomenon of aging are already clear. Among other things, some myths about the aging process already have been exploded. We know, for instance, that older people *can* learn new things. And we know that while the aging process does impair certain of our ca-

pacities, it can actually strengthen others. In short, we know enough to be doing much more than we are now doing in this whole area, both as individuals and in our official capacities. And believe me, I include myself in that.

Public Health Should Lead

Certainly no program on aging, whether it be Federal, State, or local, can be entirely successful without the full and active assistance and the leadership of the public health profession. Yet I would hazard the guess that there are many significant activities relating to aging going on in your own States and your own communities which have not so far had the benefit of that counsel and leadership.

I suspect that there is not a person here who in a few minutes could not come up with a list of several things that could be done within his present program which would contribute significantly to the betterment of conditions for older people.

Perhaps it would be nothing more than talking about aging and its problems with some of the people who come to see you in connection with other health matters, and with State and community leaders with whom your work brings you in touch. I hardly need to point out that a good many important programs have started just as simply as that.

Perhaps it would be a re-examination of the laws of your State which directly or indirectly affect older people. It goes without saying that not all our State laws are geared to the changes that are taking place in the age distribution of our population.

Perhaps it would be the establishment of closer working relationships with institutions, agencies, and organizations which have to do in one way or another with older people—infirmaries, nursing homes, adult education centers, community centers, and recreation groups, to name a few of the more obvious ones. It should be pointed out in this connection that, in Public Law 734, the Congress has placed specific responsibility on health and welfare agencies for supervision of old-age homes,

nursing homes, and infirmaries. And it is worth noting also that already in 15 States, public health authorities are working with nursing home operators on the establishment of standards for these institutions.

Certainly, any such list ought to include making a little extra effort to keep up with the rapidly growing body of knowledge about older people themselves, their hopes and fears, their weaknesses and their strengths. This should be a must for everyone in the public health professions.

Once we understand the problem in its true perspective, we will find ways to put our knowledge to work. If we believe that the problem of our older people is in part a matter of attitude—if we agree with Shakespeare that "there is nothing, good or bad, but thinking makes it so"—then, I am sure we will be on the right track.

The Nation needs its older people. The need for their combined strength, their experience, their judgment, their wisdom will become

more and more urgent as time goes on. It is urgent now. Each of us—each according to his individual capacities—has an obligation to himself and to his country to do his part in this great human undertaking.

There is not one of us here present—and let me emphasize again that I include myself in that—who cannot start tomorrow—today—to do more than he is now doing to turn what *could* become a great national liability—our older people—into one of our greatest national assets.

Health in Defense Impact Areas, I

Inventory of Health Needs

By Joseph W. Mountin, M. D.

Chief, Bureau of State Services, Public Health Service

The Public Health Service, during both World Wars I and II, assisted States and communities to meet emergency needs. This was done by strengthening health organizations around military installations; by improving facilities for the prevention and control of epidemics, and by giving special attention to industrial and other groups important in the war effort.

We are now confronted with a situation similar in many respects to the period preceding World War II. In preparation for the special needs, the Public Health Service, a little over a year ago, established in the Bureau of State Services a unit known as the Special Projects Branch. This branch has three major purposes: (1) to assemble data on developments and needs in critical areas; (2) to act as a focal point for the collection and dissemination of information on defense-impact activities; and (3) to assist the divisions of the Public Health Service in carrying out their regular and special programs as they relate to defense work.

Area Surveys

Our first objective is to obtain basic data for critical areas and to devise a mechanism whereby health problems in these areas might be anticipated in advance of their development. Specifically, the purpose of the inventories is threefold: First, to gain a clear understanding of the nature and extent of the health problems which these communities will have to face when the defense

program swings into high gear; second, to evaluate the resources available locally for dealing with the problems; and third, to determine what additional resources in the way of manpower, physical facilities, and health organization may be necessary.

We are studying the situation in three types of critical areas—military, industrial, and target. Most of the areas which have been surveyed exhibit two or more of these

characteristics; they also contain interdependent population groupings. Beginning with a training camp, for example, we have surveyed not only the areas immediately surrounding the camp, but also communities within commuting distance. Such an area might have additional military installations, industrial plants, and large-scale housing developments. The surveys have covered existing facilities for health and medical care, water supplies, sewage disposal, refuse collection, housing, hospital beds, health organization, and special health problems.

To date, some 97 military areas have been studied and evaluated. Over half of these appear to warrant further attention from the standpoint of public health. More recently, over 100 industrial localities have been surveyed; these are now being evaluated.

In general, the surveys have shown: (1) an acute shortage of public health personnel in critical areas; (2) lack of essential physical facilities, especially hospitals, health centers, improved and extended systems of water supply, and refuse and sewage disposal; (3) a need for improved sanitation of eating and drinking establishments; (4) a need for safe milk supplies; and (5) housing facilities in many areas that present public health problems. In this connection, it should be noted that there is a growing number of trailer camps, especially in areas adjacent to military installations. Many of these trailer camps are substandard and constitute a health problem of some magnitude, particu-

larly where they are located in unincorporated places.

Two points should be stressed in connection with these surveys. First, the problems are of the same general type that normally confront health departments. However, they are intensified because of the lack of personnel to cope with them and because of the urgency of the need. Second, the critical areas are by no means fixed or static. Our military and industrial establishment is growing, and an area which is not critical today might well be an important problem spot tomorrow.

Some New Services

The Public Health Service has also expanded existing activities relating to defense and has developed certain new programs. These activities are designed primarily to augment the services of State and local health departments. In the past year, for example, approximately 50 venereal disease investigators were assigned, through the States, to areas where Army, Navy, and Air Force installations are located. These investigators are conducting interviews in the camps and follow-up case-finding activities in surrounding areas, in cooperation with the health departments involved.

Our expanded epidemiological services are designed to help meet new health problems in critical areas and to perfect a mechanism which would be available immediately to spot and arrest epidemics, both natural and man-made. The service consists of at least four important elements: effective reporting; provision of epidemiologists for on-the-ground study; laboratory diagnostic services; and personnel to institute control measures. We are concentrating now on tightening and improving the disease reporting system.

For example, it is most important that we know promptly of any unusual rise in the incidence of malaria. While the necessity of reactivating an extensive malaria control program is not anticipated, there has been some increase in this disease, occurring mainly among troops returning from Korea. Through effective epidemiological intelligence

and through alert surveillance, the problem can be closely watched, and more vigorous control measures can be instituted as circumstances warrant.

In order to help State and local health departments investigate outbreaks of disease, a corps of medical epidemiologists is being recruited, intensively trained, and attached to Public Health Service field stations for immediate deployment to areas of need. An initial staff of some 20 young epidemiologists in training has already been assigned to this program; further expansion is anticipated in the future.

The Public Health Service has also furnished consultation and assistance on specific health problems important in the defense effort. Among these are fly and other insect and rodent control measures around military and industrial areas.

Mobilization and speedy industrial expansion often create new hazards to the health of industrial workers, especially when new substances and materials are used. The Public Health Service has been studying particular industrial situations, such as the mining and milling of uranium ore and the production of jet fuels, with a view to correcting or eliminating the industrial hazards involved.

In an effort to relieve shortages, but more especially to develop additional competencies on State and local health department staffs, refresher training programs have been expanded at the Communicable Disease Center and at the Environmental Health Center in Cincinnati.

Gaps to be Filled

Perhaps the weakest link in our efforts to meet health defense problems is the most important one—the basic local health structure. Unfortunately, there are still approximately a thousand counties without even the most rudimentary organization for the provision of local health services. Many more have only skeleton staffs; hence are equipped to furnish only limited services.

The Community Facilities and Services Act authorizes the development and construction of necessary physical facilities. When appro-

priately implemented by funds, this measure should furnish a mechanism for providing physical facilities important to health. The term "services" as mentioned in the act appears to be limited to the ordinary operating requirements of such facilities. Other measures will be required to meet the needs for general public health activities.

Supplementary appropriations under the Community Facilities and Services Act did not include funds for hospital construction. However, a request for funds for this purpose—based on current survey data—will probably be made in the near future. It is well to remember that appropriations obtainable under this act are intended for use only where Hill-Burton funds are not available.

In addition to filling the gaps in our general health organization, it is necessary to build the structure for planning the health and medical aspects of civil defense. It is axiomatic that we cannot have an alert system ready to spring into immediate action in the event of attack unless we carefully plan and prepare such a system. The health department's chief need here, again, is for the personnel to plan and follow through on the civil defense measures which are assigned to them.

Other important needs are for occupational health services, especially in small industrial plants producing critical defense materials, and for programs of health maintenance and rehabilitation for older people.

Pending Proposals

Some of the gaps can be closed by a redirection of effort and by increased attention to problem areas. Others call for concerted action on a community basis. Several proposals are now pending which would help localities alleviate some of their critical needs.

For example, in the last session of Congress, the Local Health Services Bill was amended to pinpoint health needs in defense areas and to strengthen services and programs in these areas. Favorable action on this bill was taken by the Senate, but it has not been reported out of Committee by the House.

Increases in general health grants other proposal would authorize the have been proposed, with the specific Public Health Service to recruit, purpose of weighting these increases train, and assign personnel to areas in favor of defense impact areas. requiring special technical assistance from the Federal Government. Recognized Federal-State channels would be maintained in providing industrial, and target areas. An this assistance.

Planning for defense calls for the closest kind of teamwork and co-operative effort. Joint planning at all levels of government will help build the foundation of sound health defense programs suited to these trying times.

Health in Defense Impact Areas, II

Planning for Community Facilities And Services Program

By M. Allen Pond, M. P. H.

Chief, Division of Engineering Resources, Public Health Service

The President approved the Defense Housing and Community Facilities and Services Act of 1951 (P. L. 139, 82d Cong.) on September 1, 1951. Limited funds to carry out the provisions of the act were contained in the Second Supplemental Appropriation Act of 1951, approved November 1, 1951. However, construction funds at present are available only for sanitary engineering works, and for streets and roads.

Responsibilities for the administration of the new community facilities program are divided between the Housing and Home Finance Agency (HHFA) and the Federal Security Agency. In Executive Order 10296 the President, on October 2, 1951, assigned to the HHFA the responsibility for programing, making loans or grants for, and (where needed) the direct Federal construction of all community facilities authorized in the act except hospitals, health centers, water-purification plants, interceptor sewers, sewage-treatment plants, refuse-disposal facilities, child day-care centers, recreation facilities, and libraries.

The responsibility for programing and making loans or grants for the latter facilities rests in the Federal Security Agency, and the Surgeon General of the Public Health Service is specifically responsible for that part of the program involving hospitals and health centers, water-purification plants, sewage-treatment plants, including interceptor sewers, and refuse-disposal facilities. The Housing and Home Finance Administrator must obtain the approval of the Surgeon General for all water-source development projects to re-

ceive assistance under the act, and he must consult with the Surgeon General on projects involving water distribution or sewerage systems.

The act provides not only for Federal financial assistance in providing facilities, but it also makes possible Federal financial assistance in the operation of community facilities. The legislative history clearly indicates that Congress did not intend that funds appropriated under this act should be used for the staffing of local health agencies such as was done during World War II

under the Emergency Health and Sanitation Activities program. The loan and grant funds available to the Public Health Service can be used to assist in the operation only of water-purification plants, sewage-treatment plants, and refuse-disposal facilities.

Responsibility of HHFA

The Housing and Home Finance Agency is the Federal agency primarily concerned with the national housing program. It is the parent agency for the Public Housing Administration, the Federal Housing Administration (FHA), and the Home Loan Bank Board. Furthermore, the Community Facilities Service, formerly a part of the old Federal Works Agency, somewhat more than a year ago was transferred to the Office of the Administrator of HHFA.

Criteria For Critical Areas

Responsibility within HHFA for its part of the community facilities program will rest in the Office of the Administrator and his regional representatives. There must be the closest possible relationship between the defense housing aspects of HHFA's program and the community facilities activities, especially as the latter involves water lines and sewers. HHFA regional representatives are responsible for both activities.

Within the Federal Security Agency the Assistant Administrator for Defense Activities coordinates all aspects of the Agency's community facilities program. In addition to the Public Health Service role, described more fully below, the Children's Bureau and the Office of the Administrator are concerned with child day-care centers and recreation facilities, respectively.

At present, the major function of the Office of the Administrator in connection with Public Law No. 139 involves representation on the Office of Defense Mobilization's Interagency Committee on Critical Defense Housing Areas, and its regional counterparts. Before Federal assistance authorized in Public Law No. 139 can be made available in a community, that community must be found to be a critical area for the following reasons: (1) A defense plant or installation must exist or be proposed; (2) substantial in-migration must have occurred or must impend; and (3) there must be a substantial shortage of housing and/or community facilities or services. In Executive Order 10296, the President placed in the Office of Defense Mobilization the responsibility for such determinations. Representation on the Interagency Committee is held by the Office of Defense Mobilization, Department of Defense, Economic Stabilization Administration, Federal Security Agency, Department of Labor, and Housing and Home Finance Agency.

Delegation of Responsibilities

Within the Public Health Service all operating responsibilities in the community facilities program have been delegated to existing organizational units. The Division of Water Pollution Control is responsible for the sanitary engineering aspects of the program, the field part of which will be directed by Public Health Service regional engineers. Although no funds are yet available for hospital or health center programming and construction under the terms of the new act, the Division of Hospital Facilities is carrying out essential planning functions at headquarters, and the regional hospital consultants are responsible for field work currently needed. Field contact by State and local health officials and hospital authorities with the Federal agencies on this program will be through the Public Health Service regional medical directors who are responsible for coordinating the various field activities within their respective jurisdictions.

All aspects of the Service's community facilities program, including

the maintenance of liaison with the Housing and Home Finance Agency, are coordinated in the Office of the Surgeon General.

Loan Steps Listed

It might appear to be simpler—at least on paper—if one unit were responsible for all aspects of the program. However, by integrating this defense activity through existing operating units we are convinced that less violence will be done to our continuing programs than if a new organization were created.

What steps must be taken before loans or grants can be made for community facilities?

1. Responsible local public officials, usually the mayor, county commissioners, or common council, will make an official request to the chairman of the Advisory Committee on Defense Areas to have the community declared a critical defense housing area. Based on analysis of data submitted—and supplemental facts collected as needed—the advisory committee will make findings and recommendations for action by the Director of Defense Mobilization.

2. In an area found to be critical, the Housing and Home Finance Agency will program the construction by private enterprise of essential rental and sale dwelling units, relaxing regulation X to assist builders to proceed. (The act provides that no permanent public housing can be programmed until the end of a waiting period of 90 days, and then only if it is clear that private capital cannot meet the housing shortage.)

3. A community in need of expanded facilities will ask HHFA or the Federal Security Agency for Federal financial assistance. First notice of the need for Federal assistance will probably come through personal inquiries or a letter from a responsible local official to the Housing and Home Finance Agency, the Federal Security Agency, or directly to the Public Health Service. At that stage we will request certain minimal information from the municipality before an application blank is furnished to it. The purpose of this is to make it possible for municipalities to save the substan-

tial sums of money that would be required to file formal applications. Formal applications will be requested only if it appears on the basis of this preliminary screening that the community will qualify for Federal financial assistance.

4. Once application forms are submitted to the community, the Public Health Service regional medical directors will inform State health officers that the municipality is planning to make application for a loan or grant or for direct Federal construction, and will ask the State health agencies at that time to make recommendations with respect to the project in question.

5. Completed application forms will be sent to FSA (PHS) regional offices or those of HHFA where they will be carefully screened. Regional officials will then make their recommendations to headquarters for final action. With limited funds, it obviously will be necessary to handle applications on a priority basis.

6. When an application is finally approved, advances of funds will be made to the municipality which thenceforth will be responsible for carrying out the job. During the construction period, periodic inspections of the project will be necessary but primary responsibility for project inspection will rest with the community unless the job is a direct Federal construction operation.

Two Key Problems

Immediate problems associated with the inauguration of this program are numerous, but two stand out above all others. In the first place, there must be prompt determinations, with respect to priorities, of need for assistance in several communities where practically the only question is that Federal financial assistance must be made available forthwith. We are confronted with the question: Should we try to give token assistance in a large number of places, or should we assign priorities in terms of relative need in the defense effort? It is our considered judgment that Congress intended us to meet the real emergencies, which means that we must establish a list upon which com-

munities will be graded in terms of their relationship to the defense effort. In connection with establishing such a priority list, the advice of State health officers and their staffs will be of major importance.

The second outstanding problem that we see arises from the legislative history of the Second Supplemental Appropriation Act. At hearings last fall, Congress asked for factual information on needs of com-

munity facilities in critical defense housing areas. Studies are being made in those communities that appear to have the most critical needs, and information is being gathered on the other designated areas.

Health in Defense Impact Areas, III

Day-Care Services for Children Of Employed Mothers

By Mildred Arnold

Director, Division of Social Services, Children's Bureau

If the defense and mobilization effort continues for any period of time, the problem of caring for children whose mothers work may become an urgent one. This is an area where State health and welfare agencies can work together profitably.

The problem of day-care services for children of working mothers has been with us for many years. The Federal Government entered the picture for the first time in World War II when an unprecedented number of women entered industry. Over 3,000 day-care centers were developed during that war with funds appropriated under the Lanham Act. At the peak of this program, in 1944, these centers were caring for 105,000 children. During the entire history of the Lanham Act, over \$51 million of Federal funds were used for this purpose.

Because of the limitations of that act, there never was a full program of day care. Federal funds could be used only for group care of children. Little provision was made for infants, and no resources were developed through Federal funds for foster-family day-care homes for very young children. Nor was it possible to use these funds to develop much needed counseling services to help mothers plan for their children. Following the war, practically the entire program developed under the Lanham Act disappeared.

Now we are seeing the same problems emerge as appeared during World War II. At the height of employment, 20.4 million women

were working. Now there are 19½ million women in the civilian labor force. Some 10 percent of these women have children under 6 years of age. It is anticipated that an additional 1,400,000 workers will be needed in 1952, and a great many of these will have to be women because available labor from other groups is about exhausted.

Long Waiting Lists

Voluntary agencies and commercial centers are attempting to meet the present need for day-care services. Some voluntary agencies report waiting lists longer than enrollments. Fees charged by commercial centers are often prohibitive for

many working mothers, and standards in many are low.

Possible Expansion

The Defense Housing and Community Facilities and Services Act (P. L. 139, 82d Cong.) authorizes Federal funds for day-care centers in critical defense housing areas, but no appropriation has been made either for operation or administration of day-care centers. If the problem becomes great enough to command Federal funds, I hope two things will happen: First, that we will have a much more adequate and well-rounded program than we have had in the past, one that includes not only group centers but also foster-family day-care homes for the very young child, and counseling services for mothers; second, in the development of any day-care program, I hope there will be a very close working relationship between health and welfare departments so that the entire needs of these children will be met.

Education Needed

At present, 27 States and the District of Columbia have laws relating to the licensing of day-care centers. Health and welfare agencies should work closely together in developing standards for the licensing of such centers and supervising these facilities. There should be close working relationships with educators, too, so that these centers do not become merely custodial places but provide sound education and training experiences for children.

As one boy once said, "I am just nobody's nothin'." While mothers are making their contribution to mobilization, we certainly do not want their children to feel that they are "nobody's nothin'."

Army Giving Primaquine Treatment To All Returning Servicemen

Only one civilian case of malaria so far reported in this country is suspected of having been transmitted from Korean returnees, Lt. Col. Donald S. Myers, of the division of preventive medicine, Office of the Surgeon General of the Army, told the health authorities.

About 9,000 among the 145,000 American servicemen who had left Korea between July 1950 and mid-October 1951 were known to have malaria, Colonel Myers reported. Since it became apparent, in April 1951, that the military "had a problem on our hands," steps were taken to see that all returnees—irrespective of a malarial infection record—were given a preventive treatment course.

The preventive treatment series consists of a single dose of 1 gm. of chloroquine and 15 mg. of primaquine a day for 14 days. The chloroquine is given as soon as possible, the primaquine regimen is started whenever the servicemen reach an accessible port of embarkation in the Far East, and is continued aboard ship on the way to the west coast.

Experiments Started in 1945

Some of the background of primaquine was given on October 16, 1951, by Maj. Gen. George E. Armstrong, Army Surgeon General, when he announced that all servicemen returning from Korea would receive the new antimalarial drug.

Experimentation with primaquine dates from the end of World War II when it was included among many thousands of drugs marked for testing as antimalarial agents, General Armstrong said. Primaquine was first synthesized in 1945 by Dr. Robert Elderfield of Columbia University, working under a grant from the Office of Scientific Research and Development.

Commercial synthesis was first effected by Dr. Elderfield in March 1950, under a United States Public Health Service grant, the Army Sur-

geon General continued. Early toxicity and neuropathology studies of the drug were begun in December 1947 by Dr. Leon Schmidt of the Institute for Medical Research, Christ Hospital, Cincinnati, also under Public Health Service auspices.

Human toxicity studies and clinical investigations were begun in March 1948 among prisoner volunteers in Stateville Prison, Joliet, Ill., by Dr. Alf S. Alving of the University of Chicago, General Armstrong reported. Dr. Alving was assisted in his work by Army physicians and supported by a Public Health Service research grant. Subsequent research has been extended to the Federal Penitentiary at Atlanta. This work is under the direction of Dr. G. Robert Coatney of the National Institutes of Health, Public Health Service. It is a joint project of the Public Health Service and the Bureau of Prisons of the Department of Justice, and is financially supported by the Army Research and Development Board. The Army has also conducted an extensive project among malarious sections of Nicaragua, General Armstrong said.

Testing among military personnel began when twin projects were established at Fort Benning, Ga., and Fort Knox, Ky., to determine how effective the drug was in the treatment of the Korean strain of malaria, and also, General Armstrong noted, to investigate the possibility of undesirable side effects when primaquine was administered to healthy men engaged in normal activities. In October, 2,700 soldiers returning from Korean duty were administered the 14-day series, aboard transport, by Navy physicians of the Military Sea Transport Service.

General Armstrong said that the Fort Benning studies were supervised by Dr. Coatney, serving as a consultant to the Army Surgeon General. Dr. Alving initiated the Fort Knox tests, now under the supervision of Dr. Ralph Jones, Jr., of the

During their annual meeting, the State and Territorial health authorities were brought up to date on the military, civilian, and research aspects of malaria control in light of infections and relapses developing among United States troops returning from Korean duty.

*In August of 1951—following discussions in Washington among the Armed Forces, the Public Health Service, and the National Research Council—the Public Health Service advised State and Territorial health authorities and editors of medical journals of this potential hazard to civilian health, pointing up the need for diagnostic facilities, drugs and treatment schedules, and methods of preventing the spread of malaria. Even prior to this, however, work had been intensified by the Army and the Public Health Service on development of the new antimalarial drug, primaquine. In November 1951, Young and Burgess reported on the susceptibility of *Anopheles quadrimaculatus* to Korean vivax malaria (Public Health Reports, January 1952, pp. 14-16). On page 200 of this issue appears a chart showing the current trend in malaria morbidity in the United States.*

In addition to the malaria reports, two condensations of reports on the heart and one on fluoridation are presented in the following pages.

University of Pennsylvania, and supervised the transport series.

Primaquine Not a Preventive

The Army Surgeon General emphasized that primaquine is not a preventive for malaria. Neither is it a substitute for chloroquine as a suppressant in malarious areas. Instead, he said, it is an effective therapeutic agent against malaria when the parasites which cause the disease have lodged in the liver or

other body organs. It is therefore expected that the serviceman who has been exposed to malaria will be cured before an attack of malaria or before relapses of the disease can occur.

Although field trials have been limited, it seems probable that malaria incidence in returnees to the United States can be sharply reduced with primaquine, General

Armstrong felt. In addition, it should be possible to avoid relapses in cases where an acute attack has already taken place, he said.

General Armstrong said that the move to administer primaquine to all returning Korean servicemen had been endorsed by both the Subcommittee on Malaria of the National Research Council and by the Armed

Forces Medical Policy Council. He predicted that the program being put into operation would prove effective but emphasized that further research would be necessary to determine finally the dose needed for the most rapid cure. Investigation of the drug is continuing at a number of Army posts and under Public Health Service auspices.

CIVILIAN CONTROL

Possibility of Malaria Endemicity Much Less Than in 1945-47

Reviewing the potential impact on civilian health of the introduction of malaria from Korea, Justin M. Andrews, Sc. D., of the Communicable Disease Center, Public Health Service, said that up to late October there had been some 5,127 cases of malaria reported from all the States except New Hampshire and Vermont.

About 70 percent of these were military cases, Dr. Andrews noted. Of the 1,233 civilian and unknown cases, about half have been appraised by State and Federal epidemiologists, and 424 were found to be parasite-positive cases. Almost all of the cases were *vivax* infections.

Dr. Andrews said that most of the military personnel who were not under military supervision when they had their attacks or relapses sought treatment from private clinicians. He estimated that only about half of the cases which have oc-

curred, according to military records, have been reported through civilian health channels.

Even so, a number of authorities have agreed, according to Dr. Andrews, that the possibility of re-establishing malaria endemicity now is not great in comparison with the situation of 1945-47 when more than 100,000 infected persons with symptoms of malaria returned from overseas to the United States.

"This and subsequent influxes of malaria-parasitized personnel can be contained without the re-establishing of malaria endemicity," Dr. Andrews maintained, (1) "if blood from suspected cases is examined in competent laboratories to determine whether or not it is malaria parasite positive"; (2) "if patients believed to have malaria are treated energetically with effective antimalarials"; (3) "if cases are reported promptly to local health authori-

ties"; (4) "if these cases are investigated and appraised epidemiologically"; and (5) "if in cases found parasite positive DDT spraying or mosquito-proofing is done on all premises within a mile of the home of these persons."

Dr. Andrews pointed out that the systematic investigation and appraisal of reported or other suspected cases of malaria, and the entomologic and spraying activities carried on around confirmed cases is known as the malaria surveillance and prevention program.

It was Dr. Andrews' belief that "this procedure, if faithfully followed, will prevent the establishment once more of malaria endemicity of this country. The States and the Federal Government have invested something more than \$50 million between them in malaria control and eradication since 1942. Proved malaria as a public health problem has disappeared—and in some States the malaria eradication criterion of the erstwhile National Malaria Society has been fulfilled. Laxity in preventing the return of this disease after so much has been accomplished would be costly and disastrous."

MALARIA RESEARCH

Primaquine 15 mg. for 14 Days Cures "High Percentage"

The new antimalarial primaquine in a dose of 15 mg. daily for 14 days has cured "a very high percentage of relapsing Korean *vivax* malaria" cases, G. Robert Coatney, M. D., of

the National Microbiological Institute, Public Health Service, reported.

Dr. Coatney described primaquine (SN 13,272) as an 8-aminoquinoline compound which belongs to the

pamaquine (plasmochia), pentaquine, and isopentaquine group of compounds, the members of which differ only in the characteristics of the terminal amino group.

Primaquine was first tested against malaria in men by Alving and his coworkers in 1948, who have shown that on an equal weight basis primaquine is approximately four times as active as the best of the other members of the group, and the

toxicity on a quantitative basis is about equal.

However, Dr. Coatney pointed out, there was not by the winter of 1950 sufficient information to allow for the use of the drug on a large-scale basis. This was the situation when an ad hoc committee of the National Research Council met to discuss the status of antimalarial drugs, with a forward look as to what might be needed as a result of the Korean developments.

It was decided then (December 29, 1950) to bend research efforts toward the complete documentation of certain 8-aminoquinolines in terms of their military application. Work has gone forward, Dr. Coatney said, at the University of Chicago installation at Joliet, Ill., and at Atlanta, Ga.—the work being spread out because one installation working by itself could not turn out the data in the time allotted.

In addition to toxicity studies, it was decided to evaluate three regimens in the treatment of relapsing cases at Fort Knox and Fort Benning. Tests were later made aboard transports returning from Korea. On the basis of these studies it was concluded, Dr. Coatney said, "that it was practical and safe to administer primaquine at 15 mg. single dose daily for 12 or more consecutive days to men of different races."

DENTAL HEALTH

Tasks of State Health Departments In Developing Fluoridation

At the present rate of progress in the fluoridation of public drinking water supplies it will take 150 years to complete the task ahead, John W. Knutson, D. D. S., chief, Division of Dental Public Health, told the State health authorities.

There are approximately 16,750 public water supplies in this country, of which some 15,000 do not contain natural fluorides. At present, 138 of these 15,000 communities have controlled fluoridation programs. However, only 80 of them started their programs within the last 12 months, Dr. Knutson reported.

Ninety-three percent of all public water supplies are in communities of 10,000 population or less, he pointed out, which means that in 9 out of every 10 cases a trained water works engineer probably will not be operating the local plant. This is of importance to State health departments, said Dr. Knutson, for they will have to provide dentists and engineers to participate in public discussions of fluoridation and to establish on-the-job training or training centers for water-works operators. They will also have to be a source of competent technical advice to help communities solve installation and operational problems. Dr. Knutson felt that this was an unusual opportunity for State health departments to offer an important service unit to virtually every community in the State.

The basic minimum fluoridation staff, according to Dr. Knutson, would include at least one dentist, one sanitary engineer, one chemist, and one subprofessional technician. They would be occupied to a large extent with training local personnel and in assisting them in getting ready for the fluoridation job.

Tasks For Staff Dentists

Dr. Knutson outlined the following jobs on which an additional staff dentist is needed to assist the State dental director in laying the groundwork and establishing a smooth-running fluoridation program:

1. Collect, analyze, and organize all scientific data relating to controlled fluoridation, and maintain a current file, including background material, technical bases of operations, results of pilot projects, types of fluoride-feeding equipment, fluoride compounds available for use, and costs.

2. Supervise the development of education materials for dentists, other professional personnel, and the lay public.

3. Encourage the dentists of each community to plan and schedule a meeting of local dental, medical, and other professional health personnel to discuss all aspects of fluoridation and consider the formulation of recommendations for its use.

4. Encourage and assist representatives of local service organizations in planning and scheduling meetings for public discussion of water fluoridation and provide for the participation of informed dental and other technical personnel.

5. Provide for a preliminary survey of the community's water supply so that useful estimates of equipment needs and costs can be made available for use at meetings scheduled for discussion of fluoridation.

6. Provide expert technical services to communities which have formally decided to fluoridate their water supplies.

7. Provide expert advisory and emergency services to communities after fluoridation has been initiated and as operational, fluoride-testing equipment, and supply problems arise.

8. Provide for the collection of baseline data on dental caries so that a periodic evaluation of the effects of fluoridation can be made in each community. Promote the use of standard record forms and provide advisory services relating to the processing, analysis, and utilization of the data collected.

9. Coordinate all promotional efforts relating to fluoridation and assume responsibility for establishing and maintaining a close and effective working relationship with the sanitary engineering and laboratory divisions of the Department.

Other Services Needed

Without essential chemical and engineering services, the fluoridation program can be seriously ham-

pered and delayed, said Dr. Knutson. He listed the following as services which the additional personnel should be able to provide:

1. Chemical analysis of the drinking water supply, including fluoride determinations.

2. Study and analysis of sources and capacity of water supply, consumption rates, purification methods, types of distribution systems, and population trends.

3. Determination of the point in the water-processing system where fluoride compounds can be added most effectively and efficiently, the

compounds most suitable, the type of fluoride-feeding equipment to be installed, and the effectiveness of proposed controls for maintaining the proper fluoride concentration.

4. Determination of storage facilities necessary for maintaining an adequate supply of the fluoride compound and the needs for auxiliary equipment to insure adequate protection of operators who handle the fluoride compound.

5. Determination of points in the distribution system where samples should be collected for testing, and training water-works personnel to

make tests for determining fluoride concentration.

6. Specifications for equipment, approval of plans, and inspection of completed installations.

7. Orientation and training of water-works operators and personnel in the hazards of handling fluoride compounds, how the hazards can be eliminated, and how to feed fluorides properly.

8. Periodic determinations of fluoride concentrations at the State health department laboratory so as to check the results of tests made by local water-works personnel.

HEART DISEASE

Diagnostic and Surgical Services Suggested on Regional Basis

Cardiovascular surgery has reached a point where at least five types of heart defects present at birth can be corrected by the surgeon's knife, Willis J. Potts, M. D., chief surgeon of Children's Memorial Hospital, Chicago, and associate professor of surgery, Northwestern University School of Medicine, said in reviewing progress in heart surgery. He pointed out, however, that the diagnostician still played the key role in moving such patients along toward surgery and correction.

Need Central Services

Citing increasing survival rates, Dr. Potts underscored the need for further development of diagnostic and surgical services for children. While a heart surgery center in every city would not be feasible, he felt the establishment of regional centers in major universities and large clinical centers would provide a means for effectively bringing such skills within the reach of every patient who needed them. Such centers, he said, also would serve to maintain the interest and skills of the specialists.

Listing the diagnostician as most essential in the staffing of such centers, Dr. Potts stated that, in addition

to congenital heart disease, the diagnostician should be familiar with rheumatic heart disease and functional murmurs, and should be able to differentiate operable from inoperable cases. Ideally, he said, the diagnostician should be a pediatrician, for murmurs and heart conditions in children may differ considerably from those in adults.

Obtaining suitable surgical skill by comparison is not too great a problem, he said. A well-trained surgeon can acquire more quickly the new surgical techniques than a physician can acquire the experience necessary for expert diagnosis.

A roentgenologist acquainted with heart disease and interpretation of electrocardiographic film (particularly in children) and an anesthesiologist who is also a physician and certified by the Board of Anaesthesiology were listed as other necessary team members.

Experience Cited

He stated his Children's Memorial Hospital team alone performed over 500 congenital heart operations, with the most common group that of patent ductus arteriosus (where the prenatal shunt has failed to close

off at birth) and tetralogy of Fallot (involving a stricture of the pulmonary artery). The latter type is popularly known as the "blue baby."

Three other types of congenital defects corrected by his group are: (1) coarctation of the aorta (involving a narrowing of the principal artery); (2) the aortic ring (several types which include deformities of the aorta and its branches); and (3) pulmonary stenosis (malformation of the heart valves, also producing a "blue" effect).

"In the approximately 168 cases operated upon for patent ductus by us, we have had no deaths," he reported. "The blue babies, however, represent an altogether different problem. In the children below 3 years of age, operated upon because they cannot live without surgery, the mortality continues at about 22 percent."

Low Mortality Rate

"In approximately 200 cases between 3 and 16 there have been only 4 deaths, or a mortality of a little over 2 percent. If the child can reach the age of 3 years, his chances of surviving surgery for pulmonary stenosis are approximately 97 percent."

Dr. Potts cautioned that not all such heart defects are amenable to surgery. Two out of five "blue babies" had to be turned away by his surgical team because operating technique has not advanced to a stage where their defects can be corrected.

Community Requirements for Developing Heart Programs

The difficult task of translating our present knowledge of the heart diseases into action presents a challenge and an opportunity, declared T. Duckett Jones, M. D., medical director of the Helen Hay Whitney Foundation.

Tracing a history of significant events in the heart disease field, Dr. Jones stated that a strategic position in progress in community heart programs has been reached. To the fund of knowledge already available, research is rapidly adding new knowledge. Also, important general recommendations have been formulated as guiding principles in the development of control programs.

Integrated Approach

Dr. Jones noted four viewpoints common to planning and advisory groups in both public and private programs at the national level which he felt offer great reassurance to those developing community heart programs and to citizens in general. First, he said, there has been no tendency to direct or to be mandatory, but rather an attempt to achieve general helpfulness and mutual cooperation. Second, all groups have stressed the importance of local initiative and local decision concerning plans and programs. This is considered essential, Dr. Jones pointed out, because of the varying

needs in the individual States and communities.

Third, there is a desire to be certain that whatever is done is in addition to and not a substitution for what already exists, so that improvement and not replacement will result. Fourth, he said, a strong feeling is held that it is necessary to bring together at the State and local levels individuals with broad professional training and interests, and many of the prominent laymen, as members of advisory committees.

Main Requirements

Dr. Jones stressed the importance of thorough orientation with regard to local conditions, facilities, and needs, and an awareness of available resources, public and private, which can be pulled together through good leadership and utilized to meet the total disease problem. With such intimate knowledge, he stated, it is possible not only to begin intelligent action to meet the gaps and needs, but also to set the mark for high standards and quality of services.

Education and training—for physicians and other professions, for the patient, and for the layman—are activities of the highest importance. Pointing out that difficulties are often caused when lay education exceeds professional education, Dr. Jones advocated special emphasis on the latter. The chief problem in professional education has been dif-

ficulty in reaching physicians who need it most. It is hoped, he said, that the *Heart Bulletin* which is expected to appear in 1952 will serve a tremendously useful function. Slanted toward the general practitioner, the *Bulletin* is expected to have content of a very high order, in such form as to "catch the physician's eye."

Case finding is another essential part of a community heart program, Dr. Jones stated. Many methods exist: first the physician and the patient; then nurses, social workers, clinics, schools, teachers, school physicians; industrial, insurance, and selective service examinations; and multiple screening. With regard to selective service, pre-employment and insurance examinations, which are confidential, Dr. Jones urged that some way be worked out whereby the individual examined can be informed of abnormal findings and directed to his physician.

Other points stressed were that supplemental clinics, important as a part of care service as well as case finding, should be used in connection with much broader opportunities for service; and that arrangements for definitive care and service must be made in the local community, notwithstanding where the responsibilities lie. Dr. Jones also emphasized the importance of prevention and the vital necessity of attention to the problem of rehabilitation. He further suggested that a register of heart cases could serve a useful purpose if used as a means to make sure that individuals receive needed services at a given time, rather than merely as a device to collect statistics.

PHS Epidemiologists Aid States

During 1951, the Public Health Service's Communicable Disease Center at Atlanta, Ga., expanded its epidemiological assistance to the States by establishing an epidemic intelligence service, a special corps of 21 communicable disease investigators. During the year, Public Health Service epidemiologists aided State and local health departments in dealing with 88 epidemics and disease outbreaks and one disaster, the Kansas flood. The epidemics included 16 outbreaks of poliomyelitis, 11 of infectious hepatitis, 6 of gastroenteritis, and 55 epidemics or individual cases of 25 other diseases.

Research for Improved Nursing Practices

By LUCILE PETRY, R. N., M. A., MARGARET ARNSTEIN, R. N., M. P. H.,
and PEARL McIVER, R. N., M. A.

In the year ahead, what can we expect from the profession of nursing in the way of progress toward more satisfactorily meeting the needs of people for service?

One important development, which will bear watching during 1952, is the trend toward analyzing all phases of nursing care—the techniques themselves, the amount and nature of the service provided, the administration of this service, and the education which prepares nurses to give it—all culminating in a study of the effect of nursing services on individual patients and population groups.

Last November the American Nurses Association reported that its clearinghouse for nursing studies had recorded and reviewed over 400 projects under way, analyzing a wide variety of aspects of nursing. What is significant, however, is not the number of studies, the sizable amounts of money appropriated for research in the nursing field, nor the number of people involved in survey processes. What is significant is the fact that the propelling force behind all this activity is the earnest desire to mold nursing into the shape of things to come, the desire to make the profession a continuing dynamic force in the total health program.

Analytical studies have grown out of the need to find practical ways of relating nursing to the increasing complexity of health services and of utilizing most effectively and economically the available nurse supply in the face of increasing

demands. Although the majority of studies are nurse-initiated, all involve the cooperation and participation of doctors and hospital or health administrators, and of other groups, such as social scientists and industrial-management engineers. All are long range, but this year and each year the data developed will add to our knowledge of how nursing service may keep moving forward in the interest of better patient care.

Studies of nursing functions and administrative studies comprise the largest areas of investigation. Both are fundamental to improving the nursing aspects of the therapeutic and preventive programs.

Analyses of Nursing Functions

In 1950, the American Nurses Association launched a "Five-Year Plan" for research in nursing and authorized that special funds, obtained from voluntary membership contributions, be set aside for this purpose. The program was in response to requests from the membership for studies which would help determine what nursing functions should be in terms of new patterns of medical care and use of new types of personnel, and also to determine the number of hours of care needed per patient per day under different circumstances.

A system has been worked out through which hospitals, universities, State nurse associations, and other interested groups may submit a nursing-study design to the ANA through the State nurses association. The plan will be reviewed by the ANA's Technical Committee on Research and, if approved, the ANA may issue a grant from its special fund to finance the proposed research. Further, the ANA will coordinate the individual studies into an integrated whole, benefiting the entire nursing profession, and

Miss Petry, chief nurse officer of the Public Health Service, is an Assistant Surgeon General and an associate chief of the Bureau of Medical Services. Miss Arnstein is chief of the Division of Nursing Resources, and Miss McIver is chief of the Division of Public Health Nursing.

report, interpret, and implement the coordinated findings to all interested groups. For the time being, grants are being limited to functional analyses of the job of nursing personnel in hospitals.

Although many individual institutions have undertaken time and function studies, the ANA program is the first attempt on a national basis to focus the research spotlight on common problems in an effort to find common solutions.

Acknowledging the responsibility and prerogative of the profession to undertake research in nursing functions, the ANA defined the broad purpose behind such studies as follows:

1. To improve nursing care and to utilize nursing personnel economically and effectively by determining functions and relationships of institutional nursing personnel of all types—professional nurses, practical nurses, auxiliary workers.

2. To determine what proportion of nursing time should be provided by each group in various situations.

3. To develop techniques which can be applied to all hospitals, and thus obtain a national picture.

The association foresaw that it would be necessary to establish a relationship between all nursing functions before it would be possible to obtain complete knowledge of professional nursing functions, and also that fact-finding must cover all nursing positions in hospitals and in all clinical fields. It also recognized the fact that job satisfactions, personal relationships, and factors motivating job changes may contribute to the determination of professional nursing functions. These assumptions shaped the master plan under which proposals for research are being considered.

One proposed study which has already been authorized will determine current practices of professional nurses, practical nurses, and auxiliary personnel in a representative sample of hospitals. From the findings, it is intended that recommendations will be made as to the proper distribution of functions among all types of nursing personnel in hospitals.

Another study proposes to develop norms for good nursing care, to experiment with the team approach in nursing—including practical nurses and nonnursing personnel—and to im-

prove techniques. It also intends to explore in-service education and to establish criteria for evaluating this in terms of improved service to the patient.

Studies such as these are expected to offer valuable clues to new staffing patterns in which the functions of the professional nurse would be those for which professional nursing skills are necessary, patterns which would result in more effective care for patients and possible savings in the total cost of staffing. It can also be expected that when we have defined current practices and have examined them in relation to the needs of patients we will learn how the basic and advanced curricula may be revised to keep nursing education in step with changing concepts. And, by knowing the number of nursing hours required per patient per day, we can estimate not only the number of nurses and other personnel needed but also the types of persons we need to recruit.

Some studies will afford the individual nurse the opportunity better to understand her role on the nursing service team; some will lead to assignments which challenge her professional potentialities beyond her present role. Thus, research can contribute both to the personal security of nurses themselves and to the satisfactions of nursing as a career.

Administrative Studies

Research in nursing administration is being conducted in hospitals and in public health agencies. A wide variety of studies are in process, the majority designed either to evaluate the cost of nursing service in terms of the kind of care provided, or to determine the effect of interpersonal relationships in nursing service, or to measure the activities of nurses in management roles in hospitals. This paper will attempt to mention only a few which are typical.

Public Health Nursing Studies

Immediately following the war, public health nursing agencies through their national organization, the National Organization for Public Health Nursing, took steps to analyze the costs of public health nursing services. The NOPHN launched a study to develop cost ac-

counting methods for public health nursing service in visiting nurse associations and health departments (1). When this method was applied in 73 agencies across the country, many interesting facts were revealed. There were striking differences in costs in different agencies, the reasons for which were not all revealed by a superficial study of the data submitted. Differences in salaries—the largest item in each budget—did not account for the entire difference in the cost of an item of service, such as a home visit, or the nursing service cost per patient-clinic visit.

The cost study of these first 73 agencies provokes many questions. For example, on the average does the agency which spends a longer time in preparation and a shorter time in the actual visit accomplish more with its patients than the one with shorter preparation time and longer visiting time? Is the average length of visit in an agency an index of effectiveness? Is the cost per individual attending group conferences any indication of the quality of services rendered? These and many other questions await investigation.

Another analysis recently completed is "A Study of Combination Services." There are at present over 40 agencies in this country in which the health department and the visiting nurse association have joined forces. This movement has been growing very slowly over the past 20 years, and the study of five successful amalgamations was made in order to disseminate information regarding patterns which had worked. This analysis and its widespread distribution may stimulate many communities to consolidate two or more public health nursing agencies into one (2).

Continuing analyses of the services offered in public health nursing programs are carried on constantly through study of annual reports in relation to local morbidity and mortality statistics. Special case-load studies are conducted from time to time in many agencies. As a result, public health nursing is shifting emphasis to care of chronic illness, home care of patients who in former days would have remained in hospitals, and to prevention of home, farm, and school accidents. In several agencies, the investigation by public health nurses of fatal home accidents has led to a great increase in

the reporting of accident hazards by the nurses and in the number corrected. This is another example of the increased awareness of community needs which studying a problem gives to the investigator.

With the ever-expanding program of services in public health agencies, there is need for studies to evaluate the demands made on nursing time in the maintenance of maximum effectiveness in both the established and proposed programs. In the past 2 years, the Public Health Service has contributed to two such studies in venereal disease case finding (3). In North Carolina, the study was concerned with priorities in nursing time for venereal disease service in a generalized nursing service. In Mississippi, the study had as its purpose the determination of the needs in the maternal-child health program to prevent congenital syphilis.

A study of the functions of nurses in industry, jointly sponsored by the Divisions of Occupational Health and Public Health Nursing of the Public Health Service, has been under way for the past year. Data have been assembled and the analysis will reveal essential information on the amount and kind of nursing service required in certain types of industries. In addition to providing essential information for industry, it will enable States and the Nation to make better estimates of their total nursing needs.

For some time, public health nurses have been questioning current practices of recording and reporting. Is there no better way of evaluating services or accounting for work done than by counting noses? So many patients seen at home, so many at the clinic, so many at the class for mothers. The number who turn up at clinic or class at least have evidenced a desire for the service. Beyond that, how have they benefited and how have those at home benefited from the visit of the public health nurse? We might make an analysis of the "satisfactory" and "unsatisfactory" conditions found on each contact with a patient. These terms, "satisfactory" and "unsatisfactory," represent the health problems the patient brings to the surface and also the ones the health worker perceives. Then, a report of the progress or lack of progress in the conditions noted might

give us some clue to what we are accomplishing.

If we can get such a measure of accomplishment and of time needed to achieve desired results with a substantial percentage of our patients, we can determine in relation to the health needs of a community how many public health nurses we should have per population unit under varying conditions.

Interpersonal Relationships

In February 1950, Dr. Leo Simmons, on a grant from the Russell Sage Foundation, began at the New York Hospital an extensive series of investigations into the problems of interpersonal relationships and their bearing upon patient welfare (4). Several of these studies are concerned with the physician-nurse-patient relationship. The premise of the studies is that if these relationships are strained or disrupted, if frictions occur and persist, the patient will suffer—just as he will benefit if, on the other hand, harmony and understanding prevail.

One series now under way is analyzing the dynamics of physician-head nurse relationship within the framework of ward routines as developed over a long period of medical practice in institutions.

Another series of studies is exploring the association of nursing service personnel with patients, including not only the head nurse but the patient contacts of staff and student nurses, social workers, technicians, and attendants. Are the working relations between patient and nonmedically oriented personnel warmer and more intimate (and perhaps therefore more constructive) than those which exist on a more formalized medico-nursing level? What effect may this situation have on patient cooperativeness and ultimate recovery? Answers to these questions are expected as the research progresses.

Dr. Simmons (4) is using the recorded interview technique for the compilation of data and has held many conferences with the nurses of New York Hospital in which he has explained both the purpose of his studies and the study method. The response from nursing personnel—all the way from the student nurse to the nurse administrator—has been enthusiastic, indicating the high regard nurses have today for

research designed to shed light on the nursing aspects of patient well-being. It is expected that some of the preliminary findings of these studies may be published during 1952.

Management Studies

Many hospitals are engaged in analyzing nursing service units to find out whether or not there is a costly misuse of professional nursing personnel and, if so, how this may be remedied. An example of investigation along these lines (prompted by the acute shortage of nursing personnel and the need for better utilization of the existing supply) is a project being conducted in selected hospitals in Michigan under the direction of Harper Hospital in Detroit and with the cooperation of Wayne University.

Other hospitals desiring to study their own situations requested the Division of Nursing Resources, Public Health Service, to devise a method of studying nursing service activities on various levels so that data may be compiled leading to changes and improvements in responsibilities and functions.

Serious consideration was given to the question of where such studies should begin. On the administrative level, with the director of nursing service? With staff nurse, at the level of closest nurse-patient contact? Or, between those extremes, with the head nurse, whose key role in ward management makes her the focal point in the kind and amount of care afforded patients?

It was decided to study head-nurse activities first, for, in the kaleidoscope of her day, the head nurse must be all things to all people, and direct services which impinge upon patient well-being. She is the doctor's most direct source of information about patients; she is the link between ward personnel and hospital management. Other departments of the hospital serve patients through her, and families and friends of patients turn to her for guidance and facts about progress and ultimate recovery. Her responsibilities range from specific problems of administration to the more subtle aspects of patient education and maintenance of a happy as well as efficient environment for everyone on her ward.

In conjunction with the Massachusetts General Hospital, the Division of Nursing Re-

sources conducted a 5-day pilot study from which a study method was developed and applied in five wards of the hospital early last year. The results of the study have been published (5) and the method has been spelled out in a manual (6) which was issued last June. This method is now undergoing extensive field trials.

The Massachusetts General Hospital study disclosed that head nurses were spending about half their time in activities related to the care of patients. It also showed that, despite the employment of clerks on the wards, a third of the remaining activities could have been performed by clerical or other personnel.

While the ratio of patient care to total time was a wholesome one, other areas of head-nurse responsibility did not show up so well. For example, she had only 14 minutes each day for making assignments, 3 minutes for supervision, guidance, and evaluation of staff performance. She was able to find only 21 minutes a day, at widely separated short intervals, for teaching students and staff; the function of patient education received only 10 minutes of her time. However, observation of patients revealed well-cared-for, contented patients. This raises questions as to whether our assumptions as to the proper functions of a head nurse need to be examined and revised.

When units showed a relatively low number of hours of care per patient, the head nurse was providing the necessary patient care which professional and nonprofessional (staff) personnel would have given if they had been available. She was also spending time on checking and serving trays, which might have been allocated to the dietary or other departments.

On the basis of these findings, is the head nurse's time producing dollar-for-dollar value to patients and to the hospital? Is it providing a work situation which produces satisfactions for the head nurse in terms of use of her special management skills and professional knowledge?

After participating in the study, head nurses at MGH said that they were better able to see how they could organize their plans more effectively, why they should—and how they could—delegate many of their duties, and to

recognize the need to restudy and to reorganize work schedules for ward clerks. The hospital itself was able to see that service to patients could be improved if the head nurse could be relieved of duties reassignable to clerks and other personnel, and apply that additional time to supervision of patient care and personnel administration.

Thus, with facts on how head nurses spend their time, hospitals can put themselves in the position of helping their head nurses spend it more effectively and can cooperate with nursing service administrators in an effort to develop improved methods of staffing.

Additional studies will determine how head-nurse activities have been affected by reorganization resulting from this study; one project will attempt to determine how the use of nursing service "team assignments" may alter the pattern of head-nurse activity.

During the year ahead, the Division of Nursing Resources and interested hospitals will cooperate again in further nurse-management studies. For example, during the past year, in efforts to find ways of reducing the cost of nursing service, the division raised the question of whether or not the functions now performed by supervisors might be assigned to other personnel. The position of supervisor was established when not every ward had a head nurse. However, present-day medical care, with its rapid turn-over of patients and concentration of acutely ill patients, requires that each nursing unit have a full-time head nurse. Under these circumstances, the activities of the supervisor may need reallocation. New study methods will be devised to find out whether or not this may be so and, if so, to what extent the present nursing administrative staff might be reduced or would need to be augmented.

Summary

The foregoing has presented a brief sample of the kind of analytical studies in which nurses and nursing organizations are participating. The fact that these studies utilize the research skills not only of professional nurses but of related experts—social scientists, statisticians, anthropologists, industrial management engi-

neers—shows the growth of nursing in its capacity to work with others in solving problems directly associated with the improvement of service to people. Research in nursing functions and nursing service administration gives high promise of better patient care and more economical utilization of nursing personnel in the future.

CDC Laboratory Training Courses, 1952

The laboratory training courses given by the Communicable Disease Center of the Public Health Service have been scheduled for 1952 as follows:

Bacterial diseases:

Part 1. General bacteriology, February 11-22; September 2-12.

Part 2. General bacteriology, February 25-March 7; September 15-26.

Enteric diseases: Enteric bacteriology, March 10-21; September 29-October 10.

Microbiology for public health nurses, May 19-23.

Mycology:

Part 1. Cutaneous and subcutaneous fungi, March 31-April 11.

Part 2. Systemic fungi, April 14-25.

Parasitic diseases:

Part 1. Intestinal parasites, February 11-March 7; September 2-26.

Part 2. Blood parasites, March 10-28; September 29-October 17.

Pulmonary mycoses, November 24-December 12.

Rabies, April 7-11; December 1-5.

Syphilis:

Serology, January 14-25; March 10-21; April 14-25; May 12-23; September 8-19; October 13-24.

Preparation and use of controls in serologic tests, November 3-21.

Tuberculosis, April 14-25; November 10-21.

Venereal diseases, May 12-16.

Virus diseases, March 10-21; November 10-21.

Courses in laboratory diagnosis designed for laboratory directors, senior laboratory staff members, physicians, and others of comparable professional standing:

Bacterial diseases, May 12-16; October 27-31.

Parasitic diseases, May 12-16; November 10-14.

Tuberculosis, May 19-23; November 3-7.

Venereal diseases, May 12-16.

Virus diseases, May 12-16; November 24-28.

Medical mycology: Laboratory methods, November 17-21.

Treponema pallidum: Immobilization test, May 19-23.

Tuberculosis Case-Finding Survey Program Of the Veterans Administration

By LEO V. SCHNEIDER, M. D., M. P. H.,
and MORTON ROBINS, M. S. P. H.

Taking routine chest X-rays of patients admitted to hospitals has been strongly advocated by the National Tuberculosis Association, the American Hospital Association, and the United States Public Health Service as a practicable and useful procedure. However, despite all the efforts by the national and State agencies concerned with medical care, public health, and hospital administration, limited progress has been made up to the present time in the development of a tuberculosis case-finding program in general hospitals. Only a small fraction of the general hospitals in the United States are reported to have a program in operation (1, 2).

Tuberculosis acquired by hospital personnel is usually considered an occupational disease and is therefore a financial liability of the hospital. Like any other large industry, hospitals must protect their employees from occupational hazards. When the relatively small cost of routine radiography of patients on admission to hospitals and a thorough case-finding program for personnel is compared to the expenses incurred by lost earnings, medical care, and compensation, failure to take proper steps in

prevention of "occupational tuberculosis" is incomprehensible. Nevertheless, it appears that the slow progress of general hospitals in undertaking such a program has been principally ascribed to financial considerations.

The importance of chest X-ray surveys becomes increasingly evident when one considers that in approximately one-half of all cases in which pathology is discovered by X-ray, no correlation can be established between the significant tuberculous lesions detected on the roentgenograms and any existing clinical symptoms or physical findings. Apparently, X-ray detects early structural tissue changes when clinical symptoms and physical findings are negligible or absent. Successful treatment is naturally more assured in cases diagnosed before destruction of lung tissue has taken place.

The effectiveness of a tuberculosis case-finding program has been adequately demonstrated by various reports published during the past 10 years (3, 4, 5, 6). Still, the program has been viewed with reservations by some hospital administrators, possibly because of the fact that, in the main, the findings have been based upon surveys of relatively small groups of inpatients. Our purpose in this paper is to report the results of the Veterans Administration tuberculosis case-finding program extending over a period of 18 months—from October 1, 1949, to April 1, 1951—and based upon over one million chest X-rays. As a guide to those contemplating the initiation of a similar program, we have also outlined the general procedures currently in operation in all Veterans Administration medical installations.

Dr. Schneider is chief of the tuberculosis control section, Tuberculosis Division, and Mr. Robins is chief of the biometrics section, Medical Statistics Division of the Department of Medicine and Surgery, Veterans Administration, Washington, D. C.

This study was presented before the American Public Health Association, November 2, 1951.

The Program

The Veterans Administration tuberculosis case-finding survey program began in August 1945. It was fully implemented on a broad scale, with complete reporting in September 1949. This program, particularly as it relates to the screening of in-patients, has proved to be the most effective of the several control measures adopted by the Tuberculosis Division for the protection of patients and personnel.

The program, in brief, is this:

1. In-patients and out-patients:

(a) A chest X-ray is obtained for each hospitalized veteran at the time of admission and for each out-patient at the time of scheduled examination if none has been made within 6 months. Thus, any veteran who comes for treatment or examination will get a chest X-ray if he has not had one within 6 months.

(b) Periodic chest X-rays are taken of all chronic general and neuropsychiatric in-patients every 12 months.

2. Personnel:

(a) All employees in regional offices and hospitals are given chest X-rays at the time of employment and when transferred to another installation or separated from employment. At 6- or 12-month intervals, employees are re-examined roentgenographically. In addition, hospital employees are given a tuberculin test (Mantoux) at the time of employment.

(b) For tuberculosis-control purposes, hospital employees are divided into two general groups: (1) those who are *not* regularly exposed to tuberculosis patients or contaminated materials, (2) those who are regularly exposed. Negative reactors to tuberculin among employees in group 1 receive Mantoux tests at intervals of not more than 6 months and chest X-rays at intervals of not more than 12 months. Should an employee in this group show sensitivity following a prior negative reaction, he is immediately given a chest X-ray; roentgenograms are repeated at 3-month intervals over a period of 18 months; and chest X-rays are scheduled at 12-month intervals.

For nonreactors among group 2 employees, tuberculin tests are repeated every 3 months

while the employee remains in this group. Should the test become positive following a prior negative reaction, the employee is immediately given a chest X-ray; X-rays of the chest are then taken every 3 months over an 18-month period, after which time routine X-rays at 6-month intervals are made.

3. Follow-up and reporting procedures:

(a) Photofluorography with 35-mm. or 70-mm. roll films, or 4 x 5 inch single films is used for screening purposes. Cases with suspicious chest pathology are immediately followed up with another X-ray on a 14 x 17 inch film and by careful laboratory and clinical studies. When the follow-up examination revises the initial findings, a corrected report is prepared.

(b) X-ray findings of active, inactive, and suspected tuberculosis or pleurisy are reported on a specially designed VA Form 10-2861. Positive and negative findings are tallied by each reporting installation, and a summary report, VA Form 10-7384, together with individual case reports, is submitted quarterly for review, tabulation, and analysis by the tuberculosis control section.

(c) Instructions covering the tuberculosis case-finding survey program provide specifically that no person will be admitted to the survey group if a tentative or previous diagnosis of tuberculosis had been made. Thus the program is restricted to the detection and reporting of unknown cases.

Findings

The data presented in this paper are not those obtained from the impressions of the "screening" X-ray, but have, in most cases, been verified on the basis of follow-up X-rays, laboratory, and clinical evidence. Furthermore, despite the significant number of cases of other chest pathology, such as bronchogenic carcinoma, lung abscess, bronchiectasis, cystic disease of the lung, and cardiovascular abnormalities, these diseases have not been included in this analysis since they do not enter into a tuberculosis control program. However, in many instances routine chest X-ray detects these other chest conditions at a stage early enough to per-

mit a favorable prognosis when delay in diagnosis might have been fatal.

During the 18 months of the tuberculosis case-finding survey, 1,091,708 chest X-rays were taken of patients and employees. Of this group, 6,045, or 0.6 percent, were diagnosed as having active pulmonary tuberculosis. In addition, 17,450 persons, or 1.6 percent, showed lesions which represented inactive tuberculosis, and at the time of report 7,729 individuals, or 0.7 percent, were tentatively classified as having "suspected" tuberculosis. Perhaps a clearer concept of the magnitude of the program and its effective yield, in terms of tuberculosis case finding, might be obtained if these figures are recast to present our experience for a given month. Consider these facts: On the average, over 60,000 persons are being surveyed monthly, and each month we are discovering more than 350 active cases of pulmonary tuberculosis and, in addition, about 1,000 inactive cases.

In table 1 are summarized findings for each of the three major categories of persons surveyed: in-patients, out-patients, and personnel. The highest prevalence of clinically significant tuberculosis was found among the in-patient group (7.4 out of every 1,000 patients surveyed). This yield was approximately 30 per-

cent higher than that found among the out-patients surveyed (5.6 per 1,000), and about seven times that observed among personnel (1.1 per 1,000). However, these over-all comparisons of the discovered cases per unit group X-rayed should be adjudged critically. To forecast the relative yields from routine surveys of in-patients as compared to out-patients, it is necessary to take into account the characteristics of the respective groups with reference to such factors as age, race, sex, and economic status. For example, the detailed findings presented in table 1 disclose that we actually found a significantly higher prevalence of active tuberculosis among older out-patients than among younger in-patients.

In-Patients

Approximately one-half million chest X-rays were taken on veterans in the 98 general hospitals and the 34 neuropsychiatric hospitals operated by the Veterans Administration. It is estimated that 90 percent of the total number surveyed were veterans admitted to these hospitals during the report period, the remainder being the chronic patients, predominantly psychotic, who received periodic chest X-rays.

Evidence of manifest tuberculosis, active and

inactive, was present in 11,642, or 2.42 percent of the 482,120 in-patients; and of these, 3,563, or 0.74 percent, were classified as having active tuberculosis. In addition, 4,637 patients were tentatively diagnosed as "suspected" tuberculosis cases. A sample survey of this suspected group indicated that about 10 percent of them would ultimately be found to have active disease. Thus, it is estimated that approximately 4,000 patients, or 0.8 percent of the total in-patients surveyed, were discovered to have active tuberculosis. This figure is comparable to previously published results of chest X-ray surveys on patients admitted to general hospitals. Bryant (2) recently summarized the findings in six such surveys in which the prevalence of active tuberculosis varied from 0.4 to 1.8 percent. However, as was indicated by Bryant, these data are not strictly comparable because of differences in the methods employed in classifying the patients. In the three studies in which the X-ray findings were verified by clinical and laboratory evidence, the prevalence of unsuspected, active tuberculosis was between 0.4 and 0.6 percent (3, 4, 7). In any case, it seems quite evident that the yield of unsuspected, active tuberculosis from surveying in-patients in general hospitals is at least four times, and probably as much as eight times, as high as that found in surveys of cross sections of the general population, or of large industrial groups.

Marked variation in the prevalence of clinically significant tuberculosis among in-patients in different age groups has been indicated by several investigators (3, 8). It has also been reported that with advancing age, the prevalence of tuberculosis among males was higher than among females. Moreover, Bloch and Tucker (9) found almost twice as much clinically significant tuberculosis among their Negro out-patients as among the white group surveyed. Unfortunately, our current reporting procedures do not permit the analysis of differences in prevalence according to race and sex. Comparisons are possible, however, between two groups of patients which may be considered as representing the variation to be expected with regard to age. We group separately veterans who served during World War II and those who had other periods of military service. Practically all World War II veterans are under 50

years of age, whereas the "other veterans" group is principally comprised of veterans over 50 years of age. The average age of each group is approximately 32 and 60 years, respectively. The prevalence of active tuberculosis was approximately 45 percent higher among the older in-patients (9.1 per 1,000) than among the younger group (6.3 per 1,000). Moreover, as might be expected, almost three times as much inactive tuberculosis was discovered among the older in-patients (27.1 per 1,000) as among the younger group (10.1 per 1,000). The relatively high yield of both active and inactive tuberculosis among in-patients over 50 years of age is of special significance, in view of the fact that many persons in this group with significant tuberculosis usually do not participate in voluntary community-wide chest surveys (10).

From the data assembled in table 2, it appears that the prevalence of both active and inactive tuberculosis among in-patients surveyed in our general hospitals was slightly higher than that observed among the patients surveyed in our neuropsychiatric hospitals. The lower rate among neuropsychiatric patients is probably related to the fact that the major part of this group is comprised of patients resident in these institutions for many years, who have received periodic chest X-rays. The prevalence of tuberculosis among this group should reasonably be lower than that among current admissions. It is, therefore, not proper to assume that our reported findings represent differences in tuberculosis prevalence between general and neuropsychiatric patients currently being admitted into our hospitals.

It is generally agreed that only about 15 percent of sanatorium patients are admitted with minimal disease, and about 70 percent are admitted with far-advanced disease. In our case-finding experience (table 3) 23 percent of the 3,563 in-patients discovered with active tuberculosis were classified as having minimal disease. Of special significance is the fact that only 37 percent of these in-patients were in the far-advanced stage.

Out-Patients

Over 400,000 out-patients were surveyed during the period covered by this report. Evi-

dence of significant tuberculosis, active and inactive, was discovered in 8,674 out-patients, or 2.2 percent of the total group surveyed; and of these, 2,250, or 0.6 percent, were classified as having active tuberculosis. At the time of the report, an additional 2,436 out-patients were tentatively classified as "suspected" cases. When these findings are compared with the Negroes and expectant mothers who comprised the 40,000 out-patients surveyed by Bloch and Tucker, it would appear that these two special groups of out-patients have higher tuberculosis prevalence rates than the veterans treated in our out-patient clinics (9).

The differential observed in prevalence rates among in-patients of different age groups is also found to exist to an even greater degree among the out-patients surveyed. Out-patients over 50 years of age were observed to have a prevalence rate of active tuberculosis almost twice that found among the younger out-patients (9.3 as compared to 4.5 per 1,000); and the yield of inactive tuberculosis among the older group was approximately three times that among the World War II veterans surveyed (30.8 as compared to 11.8 per 1,000).

The distribution of the 2,250 active tuberculosis cases among the out-patients, according to extent of pulmonary involvement, is given in table 3. Only 23.7 percent of the total active

cases were in the far-advanced stage, and in 29.3 percent, the disease was minimal in extent.

Employees

The program of routine chest X-ray examinations of professional as well as nonprofessional personnel employed in Veterans Administration hospitals and regional offices resulted in discovering 232 persons with active pulmonary tuberculosis among the 205,548 persons examined, a prevalence rate slightly higher than 1 per 1,000. Almost 3,000 employees were found to have inactive tuberculosis and were placed under close supervision. In addition, 656 employees were, at the time of report, classified as "suspected" cases.

No significant differences were observed in the prevalence of active tuberculosis among the personnel employed in our regional offices and those employed in our tuberculosis, neuropsychiatric, and general hospitals. However, the prevalence rate of inactive tuberculosis among personnel employed in our tuberculosis hospitals was significantly higher than that observed among employees in our other medical installations. This finding is probably related to the fact that some persons with arrested tuberculosis preferentially seek employment in a tuberculosis hospital, where they find a better understanding of the nature of their disability.

Table 3. Number of new cases of active tuberculosis, by extent of disease, found on routine X-ray of Veterans Administration in-patients, out-patients and personnel, October 1949–March 1951

Category of persons surveyed	Number of active cases	Extent of disease					
		Minimal		Moderately advanced		Far advanced	
		Number	Percent of active cases	Number	Percent of active cases	Number	Percent of active cases

The observed prevalence of active tuberculosis among Veterans Administration personnel (1 per 1,000) is similar to the rate usually reported for adults examined in community-wide and industrial surveys. This finding indicates that the extensive tuberculosis control program currently in operation has probably removed to a considerable extent any special risks attendant upon employment in Veterans Administration medical installations.

Of perhaps greatest significance is the fact that, of the 232 cases of active tuberculosis discovered among VA personnel, 151 (65.1 percent) had minimal lesions, 66 (28.4 percent) were moderately advanced, and only 15 cases (6.5 percent) were far advanced. Inquiry is being made into the circumstances which permitted these 15 employees to escape detection during the period when the disease was in the early stages.

Discussion

On the basis of our experience in initiating and supervising a tuberculosis case-finding survey among in-patients, out-patients, and personnel, it is believed that this program can only be effective when it becomes a permanent proce-

dure and is placed under the direction of a physician designated as the program coordinator, preferably one trained in the treatment of tuberculosis. Unless these steps are taken, hospitals will find it difficult to provide the follow-up work that is needed, and to correlate the efforts of the various departments of the hospital. The survey cannot be considered as a device limited merely to finding a case; the real purpose of the program is to locate all individuals with early tuberculosis and place them under proper supervision and treatment.

A continuous mass survey of a large segment of the general population, such as Veterans Administration beneficiaries, will not only reduce the incidence of tuberculosis in that specific group, but will also affect the morbidity and mortality of the general population through the removal of sources of infection. While our program has been in full operation for only a comparatively short time, the prevalence rates among our surveyed groups already appear to be on the decline. This trend is particularly evident in the decreasing prevalence rates of active tuberculosis among the employees surveyed.

Sixty to eighty million persons in this country annually seek medical care for one or more

complaints, and of these, approximately 16 million enter general hospitals. If it is recognized that the prevalence of tuberculosis among them is significantly higher than among the general population, a routine chest X-ray of these persons may be deemed an essential community health service.

Summary

1. This paper reports the findings of the Veterans Administration tuberculosis case-finding survey program extending over a period of 18 months and based upon over one million chest X-rays. The control measures and reporting procedures constituting this program are also outlined.

2. Six thousand and forty-five persons, or 0.6 percent of the surveyed group, were discovered to have active pulmonary tuberculosis. In addition, 17,450 persons had inactive tuberculosis, and 7,729 individuals were tentatively classified as "suspected tuberculosis" cases.

3. Among the half million in-patients surveyed, approximately 4,000, or 0.8 percent, were found to have active tuberculosis. Of these, 23 percent were classified as having minimal disease; 40 percent, moderately advanced; and only 37 percent, far advanced.

4. On the basis of our experience and that of other investigators, the yield of unsuspected, active tuberculosis among in-patients in general hospitals is at least four times, and probably as much as eight times, that derived from community-wide chest X-ray surveys.

5. The prevalence rate of active tuberculosis among the 400,000 out-patients surveyed was 0.5 percent. Of the out-patients discovered to have active disease, 29 percent had minimal lung involvement; 47 percent were moderately advanced; and only 24 percent were in the far-advanced stage.

6. Among the in-patient and out-patient groups, the prevalence rates of both active and inactive tuberculosis were appreciably higher for veterans 50 years of age and over.

7. Some 200,000 chest X-rays were taken of Veterans Administration employees. The observed prevalence of active tuberculosis in this group (0.1 percent) is similar to the rate usually reported for adults examined in community-wide and industrial surveys. Of the employees discovered with active tuberculosis, 65 percent had minimal lesions; 28 percent, moderately advanced; and only 7 percent, far advanced.

8. In our opinion, this program has proved to be the most effective of the several tuberculosis control measures adopted by the Veterans Administration for the protection of patients and personnel.

Terramycin for Nongonococcic Urethritis And Reiter's Disease

By R. R. WILLCOX, M. D., and G. M. FINDLAY, M. D.

The oral antibiotics, aureomycin, chloramphenicol, and terramycin, are perhaps the most effective drugs so far discovered for the treatment of nongonococcic urethritis, although there are at present insufficient data to assess their relative efficiency, both in nonspecific urethritis as a whole and in those forms in which virus inclusion bodies and/or pleuropneumonia-like organisms may be found in Giemsa-stained urethral scrapings.

Using aureomycin, Finland and co-workers (1) successfully treated 2 patients, and Willcox and Findlay (2) likewise had success with 3 of 4 patients, it being noted that pleuropneumonia-like organisms which were present in the urethral scrapings before treatment subsequently disappeared. Harkness (3) also succeeded in curing 7 out of 10 patients with this drug.

More recently, Chen and Dienst (4) reported the cases of 5 patients who improved or recovered when treated with 3 to 6 gm. of chloramphenicol. Of 12 male patients treated by Findlay and Willcox (5) with 3.0 to 15.75 gm. of chloramphenicol given over a period of 3 to 21 days, virus inclusion bodies were found before treatment in 6 and pleuropneumonia-like

organisms in 5. The disease was clinically resistant in 2, and 3 patients relapsed. Pleuropneumonia-like organisms disappeared from all patients, but the inclusion bodies persisted or recurred in 4, all of whom were considered clinical failures. The successes included 1 patient with Reiter's disease who was given 15.75 gm. of chloramphenicol over a 3-week period. On the other hand, Harkness (6) quoted Harman (personal communication) as having treated unsuccessfully 1 patient having Reiter's disease with this drug, although Korb and Brown (7), also in a single case, had steady improvement after treatment with aureomycin.

The present paper concerns the use of terramycin, an orally administered antibiotic prepared from *Streptomyces rimosus*. Twenty male patients with nonspecific urethritis, including two patients with Reiter's disease, and six female consorts were treated. The work has been controlled by the examination, both before and after treatment, of Giemsa-stained urethral scrapings.

Male Cases

Of the 20 patients treated, the urethritis was uncomplicated in 15, in 1 it was complicated by epididymitis, in 1 by chronic prostatitis, in 1 by cystitis, and in 2 by Reiter's disease. The average age was 33.9 (extremes 23 to 44) years. Treatment previously had been given to 9 patients (some patients have had more than one drug): 5 had received sulfonamides (after treatment 3 were still virus positive); 4 had received penicillin (3 were still virus positive after treatment); and 3 had received chloramphenicol, one with aureomycin in addition, after

Dr. Willcox is consultant senior assistant, Venereal Diseases Department, St. Mary's Hospital, London, and physician in charge, Venereal Diseases Department, King Edward VII Hospital, Windsor, England.

Dr. Findlay is with the Pharmacological Laboratories, School of Pharmacy, London, England.

which treatment 2 were found to be virus positive. One man, previously untreated, was receiving cortisone for rheumatism.

Before treatment with terramycin, 14 patients showed inclusion bodies and 6 did not. Both patients having Reiter's disease showed inclusion bodies, and these patients were also the only 2 to show pleuropneumonia-like organisms. Routine tests were performed to exclude gonorrhea and syphilis, and Giemsa-stained urethral scrapings were examined before and repeatedly after treatment. A routine urethral culture on blood agar was made before and after treatment on 12 of the patients.

Except for 1 patient who was given 3 gm. of terramycin over 5 days, 1 patient who was given 3.75 gm. over 4 days (which dosage was dictated by toxic effects), and 1 patient with Reiter's disease who failed to respond and therefore received 19.25 gm. in two uninterrupted courses over a 14-day period, the remainder of the 20 patients received 6 to 12 gm. of terramycin over 5 to 7 days.

Results

Clinical. All patients except one having Reiter's disease responded clinically.

Cultural. The organisms grown on urethral cultures bore no relationship either to the severity of the condition of the patient or to the outcome of treatment. Cultures were performed on 12 patients and the organisms reported before and after treatment in the number of cases concerned are shown in table 1.

Giemsa-stained scrapings. Before treatment 14 patients showed inclusion bodies, 2 with pleuropneumonia-like organisms in addition, and 6 showed neither. The 6 patients with negative test results were observed without evidence of relapse for 1 to 10 post-treatment checks: 1 patient at the fourteenth post-treatment day, and the remainder of the patients over 33 to 128 post-treatment days. The 14 patients showing inclusion bodies before treatment had 1 to 10 post-treatment checks: 3 patients at 6 to 14 days; the remainder, between 23 and 98 days. The one patient with Reiter's disease who did not respond clinically and another patient whose condition was complicated by prostatitis were pathologic failures, the inclusion bodies persisting in spite of treatment

Table 1. Findings in urethral cultures of 12 patients with nongonococcal urethritis, before and after treatment with terramycin

Type of organism	Number of patients	
	Before treatment	After treatment
<i>Staphylococcus albus</i> -----	10	8
<i>Staphylococcus aureus</i> -----	1	0
Coliforms-----	3	1
Streptococci-----	1	0
Diphtheroids-----	4	3
Saprophytes-----	1	2

with terramycin. The pleuropneumonia-like organisms disappeared at once from the 2 patients in whom they were found.

Complicated Cases

Five of the fourteen virus positive cases were complicated and are considered in greater detail.

Two patients had Reiter's disease. One, a man with a history of two previous attacks, showed conjunctivitis of 8 days' duration, an effusion into the right knee joint, and a painful elbow. Both virus bodies and pleuropneumonia-like organisms were demonstrated in the urethral scrapings. The patient was given 250 mg. of terramycin orally three times daily but, on the third day, his symptoms increased in severity and he was admitted to the hospital. Some days later the course of terramycin was resumed but there was no clinical improvement (sedimentation rate, 55 mm. in 1 hour), and the virus bodies persisted in the urethral scrapings even after 19.25 gm. had been given. The pleuropneumonia-like organisms, however, disappeared at once and the patient's urethral discharge and urine cleared. Virus bodies were still detected 52 days after the onset of treatment in spite of three sessions of artificial fever induced by intravenous typhoid-paratyphoid A and B (T. A. B.) vaccine. He was discharged from the hospital 47 days after the onset of treatment and, when seen at 67 days, no inclusion bodies were observed.

The second patient with Reiter's disease had had four previous attacks within 6 years. At the time of examination there was an abacterial

urethritis with pronounced keratoderma of the penis, but no other signs. Both virus bodies and pleuropneumonia-like organisms were demonstrated in the urethral scrapings. Preliminary local treatment with Castellani's paint for 1 week was applied unsuccessfully to the penis. The patient was then given 6 gm. of terramycin orally, over a period of 6 days. The urethritis cleared up at once and the keratosis improved dramatically, although it took virtually 26 days for the keratosis to disappear without the use of other methods. Neither virus bodies nor pleuropneumonia-like organisms could be demonstrated at any of four post-treatment checks over a period of 49 days. The wife of the patient also was examined but no inclusion bodies or pleuropneumonia-like organisms were found; it was stated that marital intercourse had not taken place during the previous 6 months.

One case of urethritis was complicated by epididymitis. Only *Staphylococcus albus* and diphtheroid organisms were demonstrated in culture, but inclusion bodies were observed in scrapings taken immediately before and during a course of 8 gm. of terramycin given over a period of 6 days. The urethral discharge disappeared at once, the epididymis ceased to be tender, and the swelling rapidly resolved. Moreover, at two post-treatment checks at 16 and 23 days, respectively, after the onset of treatment, no virus bodies were demonstrated either in the urethral scrapings or in the prostatic secretion. The female consort, although clinically normal, also showed inclusion bodies, which disappeared after 5 gm. of terramycin had been given over 5 days.

One case of a mild urethritis was complicated by a chronic prostatitis. Numerous pus cells were observed in the prostatic smear, and virus bodies were also observed. This patient, who had no history of conjunctivitis or keratosis, was under treatment with cortisone for an infected arthritis of the fingers and rheumatic pains in other parts of the body, which were controlled by this drug. After treatment with 12 gm. of terramycin over a period of 6 days, the pus disappeared from the prostatic smear, as did the inclusion bodies. Although only a negligible amount of pus was noted 22 days after treatment, the virus bodies had returned.

A further case of urethritis showing inclusion bodies was complicated by cystitis. Coliform organisms and *S. albus* were grown on culture. After 8 gm. of terramycin had been given orally over 6 days the urethritis and cystitis cleared, the coliforms disappeared from the urine, and no inclusion bodies could be observed in the urethral scrapings. The patient remained well throughout six post-treatment examinations over 56 days.

Female Cases

Eight female consorts, the average age of whom was 26.6 (extremes 19 to 44) years, were also examined. Although present in the remainder of the female patients, virus bodies were not found in two patients: One, whose consort had a nonspecific urethritis without virus bodies in the urethral scrapings, possessed a large, clean cervical erosion; and the other, the wife of a man with Reiter's disease but who denied sexual intercourse for a period of at least 6 months, had vaginal thrush. These patients were not treated. Of the six in which inclusion bodies were found, two had clean, apparently almost healed, cervical erosions, one had a mild vaginitis which responded clinically to carbarsone pessaries, although these had no effect on the virus bodies which were seen in subsequent smears, while the genitalia of three appeared normal in every way.

The immediate male consorts of four were known to be virus positive, one was virus negative, and the nature of one was unknown, although the young female concerned claimed that she had given nonspecific urethritis to three men in 2 years. These women, except one who had toxic symptoms and received only 2.5 gm. of terramycin over 2 days, received 5 to 8 gm. over 3 to 6 days and were observed for 7 to 87 days. The results of post-treatment smears of one are unknown, four responded satisfactorily, and one was a failure. The failure, who had no clinical signs although she complained of somewhat heavy and premature menstrual periods, was the wife of a man who had relapsed three times after chloramphenicol treatment and once later after penicillin. After a course of terramycin, however, he apparently responded.

Table 2. Results of terramycin treatment of 20 patients with nongonococcal urethritis and 6 female consorts

Nature of the urethritis	Number of patients					
	Treated	Observed	PPLO positive	Clinical failure (resistant)	Pathological failure	Failure rate (percent)
Virus positive.....	Male.....14	19	2	1	3	15.8
	Female.....6					
Virus negative.....	Male.....6	6	0	0	0	-----
	Female.....0					
Total.....	26	25	2	1	3	12.0

¹ The 1 clinical failure was also a pathological failure.

Cultures from the urethra and cervix were performed on four patients, and these showed coliforms, *S. albus*, and/or diphtheroid organisms both before and after treatment.

Toxic Effects

Of the 26 patients treated, 9 complained of side effects, which were mild in 7 and severe in 2, necessitating the termination of treatment in a husband and his wife. Six complained of diarrhea or looseness of stools, 4 of nausea or vomiting, 1 of water brash, 1 of headache, 1 of feeling sleepy, 1 of sore throat, and 3 of soreness or irritation within or near the rectum. Most of these symptoms were trivial in nature.

The results of treatment with terramycin are shown in table 2.

Summary and Conclusions

Twenty patients with nongonococcal urethritis including two patients with Reiter's disease, and six of their female consorts, were treated with 3.0 to 19.25 gm. of terramycin. The clinical results were excellent as only one, a case of Reiter's disease, proved refractory. Twenty of these patients showed inclusion bodies in Giesma-stained urethral scrapings before treatment, and apart from the one clinical failure who was also a pathological failure, all but two of the patients became negative with treatment. Likewise the pleuropneumonia-like organisms were banished from the scrapings from the two

patients having Reiter's disease in whom they were found.

ACKNOWLEDGMENTS

Acknowledgments are expressed to Charles Pfizer & Co., Inc., of New York, for the terramycin used in this study; to Prof. G. A. H. Buttle, of the Pharmacological Laboratories, School of Pharmacy, London, England, for permission to use their laboratories to carry out the pathological investigations, which were made with the aid of a grant from the Medical Research Council; and to Miss E. M. Howard, for her technical assistance.

Trends

Figure 1. The decline in malaria since 1940 has been rapid. In spite of the influx of new cases in military personnel who served in Korea, the number of malaria cases reported in 1951 was well below the levels of 1940 or 1945. However, the number reported in 1951 was larger than in 1950. In addition to anti-malarial measures in many States, the concept that a definite diagnosis of malaria can only be made following a laboratory examination of blood smears has tended to eliminate many who previously would have been counted as malaria cases. Careful follow-up in many States indicates that new cases of indigenous malaria are now uncommon. Under intensive study, the effect of the importation of Korean malaria, beyond an added number of cases, is not known but is probably small.

Figure 2. The incidence of endemic typhus fever, which has occurred principally in southeastern United States, has decreased. The lower incidence shown for 1951 undoubtedly has resulted from control measures applied on a fairly extensive scale in a number of States.

Figure 3. Prior to 1925, scarlet fever was a dreaded disease of childhood, and its relationship to other streptococcal infections of the throat was not recognized. In the past 25 years the number of reported cases of scarlet fever declined steadily except for the years 1943, 1945, and 1946. On the other hand, the number of reported cases of septic sore throat has increased in the past decade. Part of this increase probably has resulted from the fact that scarlet fever cases are now so mild that a diagnosis of septic throat is more descriptive of many infections.

The National Office of Vital Statistics of the Public Health Service has prepared this section.

DIPHTHERIA

NUMBER OF CASES REPORTED

RATE PER 100,000 POPULATION

Figure 4. Diphtheria morbidity and mortality: United States.

Figure 4. The marked change in incidence of diphtheria in the United States since 1920 is shown in the two graphs. The sharp seasonal rise in the fall months has al-

most disappeared and the minor upswing is due principally to a relatively high incidence in the southeastern part of the country. In other sections, incidence remains

at a low level without the usual sharp rise in October, November, and December. Both morbidity and mortality have shown the same rate of decline to remarkably low levels.

TYPHOID and PARATYPHOID FEVER

Figure 5. Typhoid and paratyphoid fever morbidity and mortality: United States.

Figure 5. The reported incidence of typhoid and paratyphoid fever, principally the former, has declined to very low levels. The usual summer peak of cases is almost non-

existent. Typhoid fever occurrence in various parts of the country is at such a low level that the disease no longer can be used as an index of sanitary conditions. Also,

typhoid fever morbidity and mortality have declined at the same rate. This indicates that the disease has not become less severe over the past few decades.

A topical and selective report of the seventy-ninth annual meeting of the American Public Health Association and related organizations, San Francisco, Calif., October 29–November 2, 1951.

The Practice of Public Health

International Health

All Races, Creeds Can Work Together for Health

Because men of all races and creeds can work together easily in the field of public health, the World Health Organization is best fitted of all international agencies to spearhead a movement for the social and economic betterment of underdeveloped countries, Frank G. Boudreau, M. D., executive director of the Milbank Memorial Fund, told the APHA.

Pointing to the danger of two contrasting worlds, the one healthy and prosperous, the other—three times as large—suffering from poverty, disease, and premature death, Dr. Boudreau declared that a program to bring hope of relief to underdeveloped countries was the only alternative to continued armament races and war.

Terming present support of WHO “unimaginative and half-hearted,” he called on the peoples, as well as the governments, of the prosperous countries to rally to its assistance. The National Health Council, he announced, has decided to organize a United States Citizens' Committee for WHO, to educate Americans in the potentialities of world health, and to show them the stake that will be lost if the World Health Organization program is inadequately backed.

If contributions to world health continue on the present limited scale, Dr. Boudreau warned, we may lose our chance to wipe out within a few years some, if not all, of the ancient scourges of mankind: malaria, plague, yellow and typhus fevers, and cholera. Present means and methods of control for these diseases are far more effective than anyone imagined possible a few years ago.

Advances at Stake

Another lost opportunity might be the chance to rid the world of the worst manifestations of the deficiency diseases—beriberi, scurvy, rickets, and pellagra—which still claim millions of victims, though brought under control in the advanced countries.

We may lose the chance, he continued, to share in building up and utilizing a great stockpile of knowledge and experience in health maintenance and disease prevention for the benefit of all countries.

At stake also is the prospect of building up throughout the world a united front against disease by strengthening weak health services and sharing personnel, supplies, and equipment. The advantage of international cooperation, Dr. Boudreau pointed out, is that experience acquired by any country can be used freely by all, and that costly equipment need not be duplicated unnecessarily.

Contributions to Peace

“We may lose the chance to build peace into the minds of men,” Dr. Boudreau declared, through failure to promote world-wide programs of mental health, aimed at replacing aggressiveness and the competitive spirit by sympathy and cooperation. “Our problem is to make the challenge of peace appeal to men more strongly than the excitement of war.”

An inadequate international program, the speaker continued, will jeopardize our chance to learn by experience how to work together, by practice in the field of health in which all men believe, and in which there is no need for competition, since the supply is unlimited.

World society in this industrial and scientific age, Dr. Boudreau concluded, cannot exist without some

This section completes the report of the APHA meeting. The first part, printed in January, covered programs and administration, public health in civil defense, food and nutrition, health of mother and child, and laboratory developments. The sources, aims, and editorial policies which shaped the report are outlined on page 97 of the January issue.

form of world government; but that government must be built brick by brick, and the field of international public health offers the best area in which to lay its foundation.

WHO Carries on 100-Year International Health Effort

The World Health Organization has inherited the responsibility of carrying on and developing further the work done in more than a hundred years of international cooperation in the control of disease. Brock Chisholm, M. D., Director-General of WHO, told a general session of the APHA.

Among the responsibilities inherited from the health section of the League of Nations, the Office International d'Hygiene Publique, and the United Nations Relief and Rehabilitation Administration, the Director-General noted, are epidemiological notification services, biological standardization, medical aspects of narcotics control, and many other functions.

The International Health Conference which adopted the constitution of the World Health Organization in 1946 added extensively to these earlier fields of work, defining health in much wider terms than ever before, and giving WHO responsibilities never before delegated to an international health agency.

While the constitution protects national sovereignties completely, Dr. Chisholm declared, it has introduced a new principle of international law which makes health regulations adopted by the World Health Assembly far more effective than previous international conventions. The 79 nations which have signed the constitution have agreed to be bound by such regulations, unless they "contract out" by notifying WHO, within a specified time, of reservations or of their intention not to accept the regulations. The difficult process of ratification by each government of an international convention is thus avoided.

WHO is not a "supranational" health agency, the speaker emphasized, but it "stands ready to help,

in whatever ways are most useful, each nation to take the next appropriate steps in the development of the health services available to its people."

The Coordinating Function

The money currently being spent on international health flows from many sources and through a variety of channels. Among these, Dr. Chisholm enumerated the United Nations International Children's Emergency Fund, the United Nations Expanded Program for Technical Assistance to Underdeveloped Countries, the United Nations Food and Agricultural Organization, the United Nations Educational, Scientific and Cultural Organization, the Technical Assistance Program of the United States (Point IV), and the British Commonwealth Technical Assistance Plan (The Colombo Plan).

WHO has great responsibility in relation to all this work, but its first stated function, Dr. Chisholm recalled, is "to act as the directing and coordinating authority." More and more this coordinating function is occupying WHO's attention and resources.

Social and Political Problems

The problems facing WHO are social and political as well as technical, the Director-General reminded his audience. Among the conditions tending to prevent effective transplantation of health techniques, he cited unstable government, obsolete land tenure systems, ignorance, poverty, low productivity, graft and corruption, excessive nationalism, excessive birth rates, and "sacred cows" of many colors, shapes, and sizes. "These are the main problems in all international work, including international health," he declared.

"We must not insist that our ways are right and best for other peoples," Dr. Chisholm asserted. "We can only help peoples to take the next steps along the pathway of their own development. . . . We may

hope that, with some assistance, their development may be more orderly, more humane, and faster than ours has been."

Full implementation of WHO's functions as outlined in its constitution is still far in the future, the Director-General acknowledged; but sane and fairly well-balanced progress is being made in many directions, all contributing toward the stated objectives of the organization—"the attainment by all peoples of the highest possible level of health."

"Sound, Constructive Vision" Of Future in Constitution

The World Health Organization is amply endowed with authority and admirably staffed for the accomplishment of its mission, in the opinion of C. E. A. Winslow, Dr. P. H., editor of the *American Journal of Public Health*. In his introductory remarks to the general session on International Health of the APHA, Dr. Winslow referred to the WHO constitution of 1946 as "a remarkable document in its breadth and vision."

The constitution is notable not only for its broad statements of objectives but for its specific mention of far-sighted functions. The inclusion of mental hygiene, nutrition, housing, accident prevention, and medical care "represents a sound and constructive vision of the public health of the future which is substantially in advance of the actual practice of most health departments of the United States."

WHO is not limited to over-all standardizing and coordinating activities, Dr. Winslow pointed out, but may also render direct service to individual nations or areas.

WHO also is authorized to conduct research, to improve standards of teaching and training in medical and related professions, and to enter the vast field of public health education.

International Health Precedents

Reviewing the half century of international public health activity which led up to WHO, Dr. Winslow cited the Pan American Sanitary

Bureau, established in 1902, as the first permanent organization created for multilateral international action, and the International Office of Public Health, set up in Paris in 1909, as the first such organization with a world-wide scope.

These agencies laid emphasis primarily on quarantine regulations, "a useful but negative function." The more modern concept of an international health program which involved cooperation in building up within each nation a sound and effective program of disease control and health promotion was first demonstrated by the International Health Commission of the Rockefeller Foundation, established in 1913.

The Health Organization of the League of Nations, however, was the first "really effective machinery for a continuing attack on the problems of disease on a world-wide scale." Though not a member of the League, the United States, Dr. Winslow recalled, was always represented on the Health Committee, the central body responsible for the health program.

Comparing WHO's \$6,100,000 budget for 1950 with the \$250,000 budget of the League's Health Organization to demonstrate the increased scale of the present program, Dr. Winslow declared that "It is not dollars which ultimately count but the men and women who spend them." He closed with a tribute to WHO's staffs, and to Dr. Brock Chisholm, Director-General, who, he declared, has molded "a weapon of great and living power for the attainment of the objectives of world health."

REGIONAL EFFORTS

Better National Service, PASB Program Aim

The long tradition of inter-American collaboration for health, when combined with the wide divergence in health conditions and in health services in the Americas, provide an ideal situation for the development of international health programs, Fred L. Soper, M.D., director of the

Pan American Sanitary Bureau, told the APHA.

Since 1949, Dr. Soper pointed out, the Pan American Sanitary Bureau has been serving as the regional office of the World Health Organization, and the programs of the two agencies are closely coordinated. Even though the nations in the Americas pay a double assessment, one to WHO and the other to its regional agency, the \$2,300,000 available for the combined WHO/PASB operations in 1951 is "entirely inadequate to the needs and opportunities of the region," he said. An additional \$2,700,000, however, is made available for supplies and personnel through the United Nations International Children's Emergency Fund (UNICEF) and from technical assistance funds of the United Nations and the Organization of American States.

Personnel Problems

Since 1918, hundreds of fellows from all over the Americas have been sent by the Rockefeller and Kellogg Foundations and by the Institute of Inter-American Affairs to the schools of public health in the United States and Canada. As a result, Dr. Soper said, a uniform approach to the problems of public health administration has grown up, which is important in getting agreement on policies and programs.

A basic principle under which the regional office operates, the speaker said, is that every activity should contribute to the development of the national and local health services within the country and should preferably result in a permanent increase in the budgets of these official services. Another basic principle is that no program not justified by the potential economic and social conditions of the district serviced should be developed. The WHO/PASB office "must not become a relief organization except in case of extreme emergency," Dr. Soper declared.

In stimulating the development of health projects in a country, the regional office is committed to the

ultimate objective of the development of general health services with well-rounded programs. Such general services require highly trained staffs and an effective administrative organization, Dr. Soper emphasized.

The failure to get adequate salaries and suitable working conditions—especially protection against political manipulation and interruption of tenure—has resulted throughout the American Republics in a "terrific" loss of trained personnel over the years, the speaker asserted. The regional office gives preference to the training of those individuals who are working under conditions which justify anticipation of long-term employment.

Though it is not possible to improve personnel for general health services, Dr. Soper said, there are a number of serious specific problems which can be solved by personnel with a short period of intensive training in the application of a single technique. The importance of such problems as malaria, yaws, yellow fever, and venereal disease, for which relatively simple and economical solutions are now available, justifies the organization of special campaigns without awaiting the development of general health services. Such campaigns are particularly important when they lead to the possibility of vector or disease eradication, Dr. Soper said.

Programs

There are in the Americas a number of exotic and indigenous diseases—such as onchocercosis, hydatidosis, schistosomiasis, and bartonellosis—which are limited in extent but which are either spreading or are potentially dangerous. The regional office, said Dr. Soper, "feels a very special responsibility for these diseases and is on the alert for opportunities to aid in studies of measures for their control and possible eradication."

Two eradication programs are under way in the Americas, he said, one for the eradication of yaws in Haiti, and the other a continental program, begun in 1947, for the

eradication of the *Aedes aegypti* mosquito. Although there seems no immediate threat of the introduction of the yellow fever virus into the United States, the time may come, he pointed out, when this country may desire to foment international programs for the eradication of other insects or diseases, in which case it would be to the advantage of the United States to have the principle of regional responsibility for eradication fully established.

WHO Strengthens National, Local Services in SE Asia

Despite tremendous public health problems and limited resources, WHO has shown that it can stimulate the governments of southeast Asia to increased efforts for the health of their people, according to Chandra Mani, M. D., director of the southeast Asia regional office.

This region, which includes Afghanistan, Burma, Ceylon, India, Indonesia and Thailand, contains nearly 500 million people, Dr. Mani noted, of whom 80 percent are illiterate. Average annual income is about 50 dollars a year, and the per capita expenditure on health is no more than 20 cents. Communicable diseases claim an enormous number of victims every year. The infant mortality rate averages about 150 per thousand. "Poverty, hunger, and disease are arrayed in force against the people."

Although there can be no quick solution to the major health problems, the regional office has achieved good results by confining its activities to a few well-chosen fields, Dr. Mani explained. WHO has concentrated on helping governments in the control of malaria, tuberculosis, and yaws, and in the field of maternal and child care. In all these programs, and in the related field of nursing, emphasis has been laid on the training of local personnel. "We conceive our function as essentially to strengthen local and national health services," the speaker said, "and to provide guidance in the sound development of national health programs."

Control Programs

As a result of WHO assistance in controlling malaria in large tracts of fertile land in India which had long been sparsely populated because of the disease, new possibilities are envisioned for colonization of neglected areas, with a substantial improvement in the food supply, Dr. Mani declared. In Afghanistan and Thailand, the success of malaria control projects launched in rural areas with WHO assistance has stimulated the governments to further efforts on an unprecedented scale.

In the field of tuberculosis, international assistance is being directed primarily to providing training facilities in modern methods of diagnosis and prevention, the speaker said. BCG vaccination, introduced into India and Ceylon in 1949, has made good progress. Of the 4 million persons tuberculin-tested in India, almost 2 million were positive reactors, Dr. Mani observed, and of the remainder about 1½ million have been vaccinated.

Another success has been the anti-yaws campaigns launched a year ago with WHO and UNICEF assistance in Thailand and Indonesia. In an area where previously the incidence of yaws was up to 20 percent, the disease has been controlled, he said.

The two great difficulties, Dr. Mani stated, have been the lack of trained health personnel and the shortage of vital supplies and equipment.

Dr. Mani noted that the question of population control is receiving much greater attention than previously in southeast Asia. "Family planning can play an important role," he declared, "but much greater research is required to develop methods applicable and acceptable to the East."

BILATERAL PROGRAMS

U. S. Point IV, Other Aid Complement WHO Efforts

The United States is prepared to push beyond the present reach of

the WHO—which is limited by the concept that no one nation should contribute more than one-third of WHO's basic budget—and is doing so in one-third of the countries of the world, through its bilateral programs, the APHA was told by Henry van Zile Hyde, M. D., director of the Health and Sanitation Division of the Institute of Inter-American Affairs, and United States representative on the Executive Board of WHO.

Coordination for programs in this hemisphere, he explained, is achieved by monthly meetings in Washington attended by officials of the United States Public Health Service and of the Institute of Inter-American Affairs, under the chairmanship of the regional director for WHO. In southeast Asia, the ministries of health in the various countries have set up coordinating committees which include representatives of WHO and United States Public Health Service officers. The international health movement is "a single unified movement pressing toward a common goal," Dr. Hyde declared.

Programs in Action

The emergency program launched during World War II by the Institute of Inter-American Affairs in cooperation with 18 Latin-American Republics has set administrative patterns and modes of action for bilateral health development, the speaker said. This program has stressed the development of local health services, environmental sanitation, training of health workers, and public health education. Dr. Hyde termed the Servicio Cooperativo, the administrative unit in which United States technicians work with the more numerous personnel of the host country within the ministry of health but under the direction of the chief of the institute field party, a "singularly significant achievement" in intergovernmental technical cooperation.

Noting that the institute paid less than \$3,000,000 to the Servicio funds in fiscal 1951, while the 17 cooperating Latin-American governments contributed a total of \$13,287,000,

Dr. Hyde observed, "This is not in the remotest sense a give-away program. It is truly cooperative effort to overcome problems that are of immediate concern to the entire hemisphere. . . ."

Reviewing bilateral health action in Greece, where United States Public Health Service officers form an important component of the Economic Cooperation Administration mission, Dr. Hyde noted as outstanding accomplishments the virtual elimination of malaria and the strengthening of the national health services, especially in sanitary engineering and nursing.

In southeast Asia, Formosa, and the Philippines, where the bilateral program also operates through ECA, emphasis has been given to malaria control. An aggressive attack is being made on trachoma in Burma, Viet-Nam, and Thailand, he said. The program also includes rehabilitation of hospitals and laboratories destroyed during the war. At the same time, the development of effective permanent national and local health services is the ultimate goal.

Dr. Hyde said that the United States Public Health Service supplies the technical support and much of the personnel for both the ECA operations—now being taken over by the Mutual Security Administration—and the programs of the Technical Cooperation Administration of the Department of State, now expanding in Latin America, Africa, the Near East, and the Far East.

Tuberculosis Key Element In Alaska's "Frontier Health"

Public health in Alaska is still "frontier public health," C. Earl Albrecht, M. D., commissioner of health of Alaska, told the health officers' section.

Foremost among the problems making for a frontier situation is tuberculosis control, Dr. Albrecht said. The death rate from tuberculosis among the native population is 600 per 100,000. The need for hospital and surgical resources is dramatized by the numbers of children crippled by tuberculosis.

Another very trying situation, the speaker said, is the condition known as "permafrost." In 60 percent of the land area of Alaska, the earth is permanently frozen a few feet below the surface. This creates problems of water supply and sewage disposal which engineers have yet to solve.

Through the cooperation of the United States Children's Bureau, the Alaska native service, the Alaska Department of Health, and the United States Public Health Service, a plan has been developed to take public health services to people scattered over great areas along the coast lines and the major rivers. Mobile health units are employed, Dr. Albrecht explained, three of these being floating health centers, one a railroad unit, and one serving the highway.

Due to the health-conscious Alaskan population, a cooperative legislature, and the support of the Public Health Service and the Children's Bureau, a well-rounded public health program is under way, the speaker said. A challenging amount of work remains to be done, he emphasized, and the rapid influx of American defense workers has raised new problems of environmental health.

3 Million Saved in Japan By Health, Welfare Action

Modern, nation-wide public health and welfare programs have saved the lives of three million Japanese during the Allied occupation, according to Brigadier General Crawford F. Sams, M. C., United States Army, chief of the public health and welfare section of General Headquarters, Supreme Commander of the Allied Powers. General Sams told the health officers' section of the APHA that the mean annual death rate of 18.7 per 1,000 population for the 7-year pre-occupation period was reduced to 10.8 in 1950.

The death rate from tuberculosis has been reduced to 145.4 per 100,000 in 1950 from the peak of 280 per 100,000 in 1945 by a control program which included the use of BCG, the general said. Immunizations for ty-

phoid and paratyphoid fevers, and improvement in environmental sanitation for the dysenteries have sharply reduced morbidity for the enteric diseases, the second leading cause of death in Japan, he added.

Organization

In contrast to the United States, where public health and welfare legislation is largely State or local, authority in Japan is derived from the National Diet, General Sams pointed out. Since there was only a primitive health and welfare organization in Japan in 1945, it was possible to establish an efficient administration pyramiding down from the Ministry of Health and Welfare, through departments in each prefecture (state) government, with health center districts within each prefecture.

Medical service districts, welfare districts, and social security districts coincide geographically with the health center districts, General Sams explained, so that the four fundamentals of health and welfare are incorporated into a single organization. Each health center district contains at least one completely organized and staffed health center and as many branches as needed.

Since there were no schools of public health in Japan, an institute of public health was established as a teaching institution. To supplement its program, a model health center which is primarily a training institution for health center personnel is located in each prefecture. In addition, General Sams stated, a school of hospital administration was established in 1948 for training directors of the 3,700 hospitals in Japan.

A national institute of health has been established, he said, which carries out research, biologics assay, and the training of health personnel in conjunction with the institute of public health. The national hygienic laboratory, charged with establishment of minimum standards and the assay of all drugs, medical devices, and cosmetics, is also directly under control of the ministry of health and welfare.

Epidemiological Investigations

IMMUNIZATIONS

Injections, Paralysis In Polio Linked

An analysis of relationships between immunization and poliomyelitis, based on a study of 1,300 children 5 years of age or less who had had poliomyelitis in 1949 and 1950, was presented by Dr. Morris Greenberg, M. D., M. S. P. H., Harold Abramson, M. D., Helen M. Cooper, and Helen B. Solomon, of the bureau of preventable diseases, Department of Health, New York City, to a joint session on immunization of the epidemiology, health officers, laboratory, and maternal and child health sections.

They felt that a relationship existed between the site of injection and the site of paralysis, when injections of diphtheria toxoid, pertussis vaccine, or tetanus toxoid had been given not more than a month before the onset of the paralysis. They did not feel, however, that such a relationship existed when penicillin or other agents had been given. No increase in bulbar cases or deaths resulted from previous injection, it was stated.

Hazard Small in Infants

Dr. Greenberg and his colleagues said that the study showed the extra hazard of poliomyelitis as a result of recent inoculations to be small in children under 1 year of age, and negligible in infants under 6 months of age.

During nonepidemic years it appears that immunizations may be given to infants under 1 year of age throughout the year, they felt. Routine immunizations may well be suspended in older children during the poliomyelitis season and extended during epidemic years to infants 1 year or more of age. Therapeutic and immediate prophylactic injections should not be discontinued at any time, they stated.

Before the same session on immunization problems, data connecting injection sites and the site of paralysis in poliomyelitis were reported by Robert F. Korn, M. D., Robert M. L. Albrecht, M. D., and Frances B. Locke, of the bureau of epidemiology and communicable disease control of the New York State Department of Health.

New York State Study

In a study designed to test British and Australian reports of an association between injection site and subsequent paralysis site, 2,137 cases of poliomyelitis in all age groups were studied. Control information covering a 2-month period prior to onset of the disease was gathered from members of the patient's household (6,055 persons) and from neighboring families on either side of and across the street (14,710 persons).

Injections were found to be nearly twice as common among poliomyelitis patients as among the controls in each age group. Of paralytic patients not injected, only 34 percent had arm involvement. Of patients with arm injections 8 to 14 days prior to onset of the disease was paralysis. Sixty-two percent of those injected 15 to 21 days before onset, and 50 percent of those injected 22 to 28 days before onset had arm involvement. The same correlation applies to leg injection and paralysis, they reported.

Adult Protection

Repeated small doses of diphtheria toxoid, either separately or combined with tetanus toxoid, may offer a more practical means of mass immunization of adults, Geoffrey Edsall, M. D., Army Medical Service Graduate School, Washington, told the session.

Dr. Edsall pointed out that the Schick test has certain limitations and presents difficulties, particularly

in mass use. The use of purified toxoid has reduced the incidence of reactions, he said.

NEW CONCEPTS

Herpangina in Children Related to Cocksackie

Herpangina, a mild disease of children characterized by the appearance of minute blisters and ulcers in the throat, is probably more widespread than has been supposed and apparently occurs in epidemic form, Roger M. Cole, M. D., Joseph A. Bell, M. D., Edward A. Beeman, M. D., and Robert J. Huebner, M. D., of the Microbiological Institute, Public Health Service, reported to the epidemiology section.

As a result of careful observation of several communities and of a variety of ill persons in hospitals over a period of 14 months, the investigators were able to confirm and to establish some definite facts concerning the etiology and epidemiology of herpangina.

Herpangina, it was reported, occurs principally in the late summer and early fall months and is spread from person to person. Primarily a disease of children under the age of 4, it has been suffered by persons up to the age of 60. Sex or race have no apparent influence on the occurrence of the disease. The length of the incubation period ranges from 1 to 10 days. Dr. Cole and his co-workers found two cases of repeat attacks of herpangina: two different types of group A Cocksackie viruses were shown to be responsible for the disease, neither type conferring immunity against the other.

The investigators reported that while the distribution of various Cocksackie viruses was fairly widespread in the communities under study, the role of these viruses in the natural causation of illnesses other than

herpangina is not yet evident. These viruses have been isolated from cases of several paralytic and nonparalytic disorders, including poliomyelitis, summer grippé, myalgia, and pleurodynia (muscular ailments), aseptic meningitis, and some fevers of unknown origin, but there is insufficient evidence at present to indicate that these viruses actually cause these illnesses.

The relation of the Coxsackie virus to poliomyelitis has been greatly overemphasized, Dr. Cole and his group feel. "There seems to be no evidence in the published literature to support the idea that Coxsackie virus occurs more frequently in persons with poliomyelitis than could be anticipated by coincidence," they said.

METHODS

Studies of Hypertension, Administrations Needed

Four significant discoveries from a review of the literature on hypertension and high blood pressure are: (1) there are no consistent standards for blood-pressure measurement; (2) there are no established criteria for defining hypertension; (3) there is no existing study on hypertension based on a scientific population sample; and (4) none of the studies indicate the actual extent of the problem, so reported E. Gurney Clark, M. D., of the School of Public Health of the Faculty of Medicine, and John A. Morsell, Ph. D., research associate of the Bureau of Applied Social Research, both of Columbia University, to the epidemiology section.

An epidemiological approach to hypertension would mean an attempt to describe its incidence, prevalence, trends, and distribution by age, race, sex, and the like, they felt, reporting on a 3-day symposium to review and to appraise the natural history of essential hypertension.

One section defined terms, established criteria, and introduced the concept of the natural history of essential hypertension. Section 2 elucidated causes. Sections 3 and

4 reviewed specific agents, the environment, and human characteristics. Section 5 gave research suggestions to fill the gaps in our knowledge as defined by the work of the previous sections, they said.

Eight basic problems, including the role of psychological trauma, heredity, and constitutional factors, the relation of blood pressure to illnesses and to normal life, as well as questions implicit in the preceding paragraphs are under study, they said.

Hospital Practice

Applying epidemiology to the field of administrative medicine is a change in subject matter only for the epidemiologist, A. Daniel Rubenstein, director of the division of hospitals of the Massachusetts Department of Public Health, said before the epidemiology section.

The value of epidemiology has been proved in communicable disease fields and is now being used more broadly in the fields of noninfectious conditions, such as alcoholism, cancer, diabetes, and other chronic diseases, he said.

In one instance, an epidemiological method was used successfully to determine the number of maternity beds needed in a new hospital. It was found that the number of beds planned were twice the number of births expected. This, in turn, led to a State-wide survey of maternity beds as well as births. Hill-Burton funds helped to standardize obstetric facilities throughout the State.

Mental Disease

As with the common cold and some other nonfatal diseases, the epidemiology of mental disease must begin with the study of cases during life, Ernest M. Gruenberg, M. D., and Bernard M. Kramer, Ph. D., of the New York State Mental Health Commission, Hilda F. Silverman, M. A., of the New York State Department of Health, and Charles V. Willie, M. A., of Syracuse University, jointly told the statistics section.

Conditions under which mental

diseases are more or less likely to occur—information vital to epidemiology—will be studied by investigation of incidence in different neighborhoods of one community, they said. Previous work indicated there are variations in the rate of mental disease hospitalizations, but did not reveal whether the variations were in incidence or use of the hospitals or both.

The group is planning to study prevalence of unhospitalized cases later. Some of the difficulties involved will be lack of awareness by the patient (as in loss of memory in organic brain disease) and attempted concealment of disease in other cases.

DISEASE STUDIES

Pleurodynia Study May Aid in Polio Problem

Because of many similarities which seem more than coincidental, the study of pleurodynia may assist in solving some of the problems of poliomyelitis, according to Alfred S. Lazarus, Ph. D., Elizabeth A. Johnston, M. S., and James E. Galbraith, M. D., of the Department of Public Health and Preventive Medicine of the University of Washington School of Medicine and Grays Harbor County Department of Public Health.

A 1950 outbreak of epidemic pleurodynia in Hoquiam, Wash., was described to the laboratory section by these scientists. They pointed out that the symptoms of pleurodynia—fever, abdominal pain, nausea, headache, stiff neck, and pain in throat, chest, and extremities—resembled poliomyelitis, without the paralysis. Almost three-fourths of the patients were under 20 years old. The causative agent was identified as a group B Coxsackie virus on the basis of symptoms and pathological changes in experimental animals.

Types of Polio Virus

Thirty-four new strains of poliomyelitis virus, representing three

TB in the Navy

An estimated 20 to 30 percent of naval personnel with tuberculosis had had X-ray examinations which were reported negative, before admission to the hospital. Upon review, however, the X-ray plates were either found to be technically unsatisfactory or to contain definitely suspicious shadows, according to Commander Sidney A. Britten, M. C., United States Navy, Deputy Director of the Preventive Medicine Division of the Bureau of Medicine and Surgery.

Although the total new-case rate for all forms of tuberculosis was low (59 per 100,000), there were marked variations for specific types of personnel. In 10 to 15 percent of the cases, contact with tuberculous friends and relatives outside the service was known.

Three new control measures applied during 1951 were: (1) routine annual chest X-ray examinations, wherever practicable, of dependents of naval personnel who are 15 years of age or over; (2) tuberculin testing and periodic retesting of naval hospital staff personnel; and (3) immediate reinterpretation of X-rays of all recruits whose tuberculin skin tests are doubtful or positive, Commander Britten reported.

Alcoholism and Suicide

Deaths from alcoholism as a primary cause during 1938-48, as recorded by the medical examiners of Massachusetts, totaled 1,555 or 3.29 per 100,000 population, said Johannes Ipsen, Jr., M. D., superintendent of the State Institute of Laboratories, Merrill Moore, M. D., associate in psychiatry at Harvard University Medical School, and Leo Alexander, psychiatry instructor at Tufts College Medical School, all of Boston, Mass.

Reporting to the epidemiology section, they said that of 106,579 medical examiners reports on death the 11-year period, 7,968 mentioned alcoholism. It was decided that where cases of alcoholics dying from other diseases or injury, they should

Alcoholism was found more frequently among persons dying from certain poisonings, particularly barbiturates. Of 1,195 persons attempting suicide, 143 were alcoholics, and 4.9 percent of these were successful in their suicide attempts. Of the nonalcoholic group, 11.8 percent were successful suicides.

Dr. Ipsen and Dr. Moore estimated an alcoholism prevalence of 1.0 to 1.3 per 100 people in Massachusetts based on the sampled violent deaths.

Lung Cancer

It is only by routine X-ray surveys that lung cancer can be discovered while still asymptomatic and in the silent and curable stage, Lewis W. Guiss, M. D., chairman, cancer committee, Los Angeles County Medical Association, told the Public Health Cancer Association.

Preliminary findings in the incidence of lung cancer through a mass chest X-ray survey of 1,867,201 persons during a 10-month period in Los Angeles was described by Dr. Guiss. Of this total, 64,745 were

asked to return for confirmatory re-examination, and 54,648 complied. The X-rays were found to be essentially negative in 14,344 of the re-examined cases. Old healed disease was shown in 9,216. Other diseases, including neoplasm suspects, were found in 5,646.

Tuberculosis and cardiovascular conditions, it was believed, were being picked up accurately, but some neoplasm suspects might be overlooked. A thoracic surgeon, plus a high index of suspicion, added to each reviewing team, raised the percentage of persons suspected of having neoplasms.

Of the confirmatory 5,646 cases of other chest disease, 3,506 were placed in the chest tumor registry. This showed an incidence rate for tumor suspects of 1.9 per 1,000 examined and is significantly higher than incidence rates shown by other chest X-ray surveys, Dr. Guiss pointed out. The total incidence of possible tumors detected by chest X-rays in 10 surveys was shown to be 0.8 per 1,000, he continued. He attributed the incidence rate of the Los Angeles

A Geiger counter of flies as part of service at the San Francisco Association. The department of Engineering Morton Go

onstrate radiation by the of the American Samuel C. server is ent

County survey to either a high index of suspicion or an actual increase of lung cancer in that area.

Lost cases were problems in treat-

ment and follow-up and were due to a number of factors, which Dr. Guiss enumerated. He presented tabulations of the X-ray findings, disposi-

tion of patients to physicians, clinics, and hospitals, and statistical classifications of diagnoses under malignant and benign tumors.

Statistical Methods

CHRONIC DISEASE

New Indices, Periodic Observations Necessary

Chronic disease is almost always not in a static state, despite the usual connotation of the word "chronic," Philip E. Sartwell, M. D., associate professor of epidemiology at John Hopkins University, and Margaret Merrell, Sc. D., associate professor of biostatistics, told a joint session of the epidemiology and statistics sections and the Biometrics Society.

They pointed out that changeability and variation in so-called chronic conditions brings up two questions for discussion: (1) the need for additional indices to describe these changes; and (2) the point that the interpretation of prevalence and incidence figures is more involved in chronic than in acute diseases.

The kind of morbidity index needed for studying a disease will depend on the purpose for which the information is to be used, and by whom, said Dr. Sartwell. The brief period of illness in acute diseases does not furnish much information of interest to an epidemiologist, but the variety of changes which occur during a chronic illness "are of the greatest relevance to our understanding of its epidemiology."

Eliminating from this discussion congenital defects and secondary physical or mental changes resulting from acute illness, Sartwell and Merrell then classified chronic disease roughly as: (1) conditions such as cancer, which progress rather rapidly and terminate fatally; (2) degenerative vascular disease, with slow progression of basic vascular episodes "punctuated by unpredicta-

ble acute episodes, such as coronary occlusion or cerebral hemorrhage;" (3) diseases like peptic ulcer, rheumatic heart disease, rheumatoid arthritis, and tuberculous infections, whose course is variable and may end in complete recovery, permanent disability, or death; (4) endocrine deficiencies, such as diabetes mellitus and thyroid deficiency, which may be controlled by substitution therapy; (5) diseases resulting from prolonged exposure to recognized environmental factor-chronic dietary deficiency diseases, chronic intoxications, and pneumoconiosis.

Other Landmarks Needed

Scales upon which to measure the rate of progression of chronic diseases throughout various stages are difficult to establish, said Dr. Sartwell. In some diseases no change except death has been classified; "yet, the longer the duration of the disease and the more variable its behavior, the greater the need for other landmarks than death in describing its course." An individual's ability to carry on his work might be a better index to disability than clinical or laboratory tests, in the authors' opinion.

Studies in tuberculosis mortality in the United States have shown that "it is the rate of progression rather than either incidence or prevalence, that furnishes the key to the . . . difference in mortality" between whites and Negroes, according to Dr. Sartwell. Progression rates are likewise needed in interpreting geographic differences in prevalence of disease, and in studying the effect of the time trend on prevalence ratios. Drs. Sartwell and Merrell felt that essentially all the problems of chronic disease revolve around

the time factor, since every characteristic by which a group of people is commonly classified, except their sex and race, can change with time.

They emphasized that, to advance present knowledge of chronic disease and better to interpret morbidity rates, there is need for more studies in which periodic observations are made of individual members of a population, rather than single surveys of prevalence, as has been done in the past.

Multiple Sclerosis

In many parts of the world today multiple sclerosis is thought to be "one of the most common chronic diseases of the central nervous system," according to Leonard T. Kurland, M. D., an epidemiologist at the National Institute of Mental Health of the Public Health Service, speaking before the epidemiology and statistics sections and the Biometrics Society.

A study was made in 1943 of the reported mortality in the United States and Canada, where language, medical terminology and practice, and hospitalization procedures would presumably be similar, in order to measure and compare the frequency of multiple sclerosis over a wide latitude. Results seemed to indicate that multiple sclerosis may be more prevalent or more severe among the white population in northern areas than in the South, said Dr. Kurland.

He reports further that intensive surveys carried out in 1949 to test the validity of inferences drawn from the 1947 analysis showed that the average annual death rate for multiple sclerosis is three to four times higher for Winnipeg and Boston than for New Orleans. Since an

apparent similarity exists between the prevalence ratio and the death rate in each of the three cities, he suggests that "mortality from multiple sclerosis may be useful as an index of prevalence," and that "the variation in multiple sclerosis distribution is related to some geographic factor rather than to differences in racial susceptibility."

Cancer Therapy

A method for measuring the effectiveness of cancer therapy, using three indices: (1) the "cure" rate; (2) the annual death rate from cancer; and (3) the percent of normal life expectancy, was presented to the statistics section and the Biometrics Society by Joseph Berkson, M. D., Sc. D., and Robert P. Gage, M. S., of the Mayo Clinic Division of Biometry and Medical Statistics.

As an illustration of their method, they divided a series of patients who had been operated upon at the Mayo Clinic for cancer of the breast into two groups, one without metastasis and one with metastasis.

The authors estimated that for the patients without metastasis, 64 percent have a normal life expectancy; for the 34 percent who were not cured the annual death rate will be 12 percent; and for the total group the life expectancy is 76 percent of that of the normal population. The results for the patients with metastasis may be similarly interpreted, but they are not so favorable.

Berkson and Gage pointed out that of prime importance is the degree of completeness of the follow-up of patients. In a recently completed follow-up of 8,000 patients surgically treated for cancer of the stomach, they obtained a trace rate of 99.4 percent for patients traced as long as 35 years.

MORBIDITY

Short-Range Predictions For Polio Described

Methods for appraising impending epidemicity of poliomyelitis and of making estimates of total cases to be reported during a year were outlined

before the statistics section by F. M. Hemphill, Ph. D., of the Department of Public Health Statistics of the University of Michigan School of Public Health.

Dr. Hemphill demonstrated application of the method to the United States as a whole and to Michigan for epidemic periods in 1950. In this method, an expected number of cases per week is developed by computing a "theoretical distribution" based on two selected years' observations. The number of cases in each week of this distribution is considered to be subject to Poisson-type variation. A variance is computed for each week from this consideration and the mean plus three times the standard deviation is established as the "upper limit" of the number of cases expected in any one week. If this upper limit is exceeded for two consecutive weeks, then the total number of cases for the year would be expected to exceed the total number of cases for the "theoretical distribution."

Four methods for estimating the total poliomyelitis cases expected were discussed by Dr. Hemphill: (1) estimation of total cases for Pearson type III relationships; (2) estimation of total cases by proportionate comparison of theoretical and current distributions; (3) Cohen's method of estimating parameters; and (4) predication of total cases by percentage increment.

California Research

A research project to develop, analyze, and evaluate methods for obtaining adequate and current data on morbidity in the general population is now under way in California, Arthur Weissman, B. A., J. D., of the California Department of Public Health told the statistical and epidemiology sections.

Following recommendations of an advisory committee of representatives from physicians' and other organizations concerned with public health, three potential methods are being evaluated: (1) the use of operating program data for projecting illness rates for the general

population; (2) household sample survey methods; and (3) collection of illness data from samples of physicians and hospitals.

Before testing one or a combination of methods on a state-wide basis, Dr. Weissman said, the advisory committee felt that potential methods should be tested on a selected area. San José was chosen, on the basis of its population, both in numbers and because its composition resembles the State as a whole, and because the area is relatively self-sufficient in medical, hospital, and related services.

Dr. Weissman described the plan for pretesting and evaluating alternate methods of measuring morbidity. He states that emphasis is placed on the verification of illnesses reported in household sample surveys, but that the need to determine the extent of under-reporting of illnesses in these areas is of equal if not greater importance.

Family Record Study

In an experimental effort to design a method of investigation useful in securing accurate and complete information on morbidity and medical care among families, the University of California conducted a family record study in 1949, E. Richard Weinerman, M. D., Charlotte F. Muller, Ph. D., and Anne Waybur, A. B., of the University's Division of Medical Care Administration and Biostatistics, reported to the medical care section.

The study sample was made up of employees on the payroll lists of the University of California at Berkeley, most of whom were young, married, employed, white-collar, urban workers. The group included more females, younger children, and larger incomes than the general population.

The method used in the study, said Dr. Weinerman, was to avoid dependence upon memory for remote events, to create a continuity between the population sample and the research team over a period of time, and to provide a means of recording and correlating many dif-

ferent kinds of interdependent health information. It included a specially designed health record booklet, regular monthly visits by a trained interviewer, and an integrated inquiry into morbidity, receipt of health services, and health expenditures.

This pilot study demonstrates, the authors conclude, that the method described may be most useful in long-term studies of specific health problems, such as prevalence of chronic disease, receipt of health services, and expenditures for medical care.

FOLLOW-UP

"Not Observed" Element Key Factor in Estimates

In measuring incidence or prevalence of disease in given groups or samples of persons, the effect on his estimates of those in the sample who are "not observed" is one of the most difficult problems the statistician has to face, Albert P. Iskrent, M. A., and Quentin R. Remein, of the Division of Venereal Disease, Public Health Service, emphasized to the statistics section and the Biometrics Society.

They saw the problem as having two aspects: (1) the effect of nonrespondents on estimates of incidence and prevalence based on case-finding projects; and (2) the effect of nonrespondents upon evaluation of therapy based on follow-up of treated cases.

According to Iskrent and Remein, evidence from several case-finding projects indicates that respondents differ from the general population in color, sex, age, education, and economic status, and that nonrespondents differ from respondents with respect to prevalence of disease.

The authors report "there were no appreciable differences between the re-treatment rates" of two groups of patients studied by the Division of Venereal Disease, one followed routinely and the other intensively.

Cancer Survival Rates

In a paper given by Mardelle L. Clark, A. B., Jean Hall Gerende, B. S., M. S. P. H., and Mary B. Peeples, of the Armed Forces Institute of Pathology, an evaluation was made of the differences in follow-up rates of patients treated for primary carcinoma of the bladder when computed by the direct and by the actuarial methods. They felt that the over-all rates did not provide a sufficient basis for prognosis, since the rates vary in direct ratio to the severity of the disease.

Actuarial Method

"The so-called actuarial method of computing survival rates is self-contradictory and, as such, cannot be used for building up a statistical theory for the evaluation of the role of chance on the varying outcomes of treatments of patients," Evelyn Fix, Ph. D., of the statistical laboratory of the University of California, maintained before the statistical section and the Biometrics Society.

She pointed out that in dealing with data on moderate numbers of individuals and in trying to use these data for comparisons either of different methods of treatment or of different systems of symptoms it is essential to have at hand an appropriate statistical theory to guard against unwarranted conclusions.

To be useful, Dr. Fix emphasized, "such theory must be based on a system of assumptions that are as close to the actual phenomena as possible, and these assumptions must be mutually consistent."

DENTAL RESEARCH

Persons, Not Teeth, Unit of Clinical Sample

"More and tighter dentist-statistician relationships are necessary in public health dentistry today," A. L. Russell, D. D. S., of the National Institute of Dental Research, Public Health Service, emphasized before the dental health and statistics sections.

Public health dentistry has three

main objectives, Dr. Russell added—education, treatment, and prevention. To reach these objectives, the dentist must know what facts are pertinent and available and how to procure and evaluate them.

In planning a program, Dr. Russell said that "it is considered good practice to make a preliminary needs survey . . . to determine the magnitude of the community problem and to determine the proportions in which education, treatment, or prevention are most applicable as a solution." He went on to say that the data "can be recorded on a single examination form . . . designed for quick tabulation and adaptable to . . . methods in common use." A specific program can then be planned to meet the actual needs of the community.

Dr. Russell cited an instance in which it was found that the referral program had failed because local dentists would not accept children as patients. After three of seven local dentists had taken a short course in dentistry for children the referral system was reinstated. Had the survey shown different findings another approach might have been used.

Successful "trouble-shooting," as Dr. Russell describes this method, is dependent upon accurate diagnoses, for, unless the raw data sent in from the field have been assembled according to well-established principles and can be depended upon they are worthless to the statistician.

Planning the Key

Dr. Russell says that "it is a truism that the statistician is more useful during the planning phase of a survey than he can be after the raw data have been assembled for tabulation and analysis." Surveys are pre-planned "from the statistical point of view." Evaluation of a given program begins with a resurvey, using exactly the same procedures as those in the original survey. The statistician then analyzes the results to determine whether the observed differences are real, and the dentist decides whether they are meaningful.

In discussing the flouridation program, the Public Health Service officer stated that "flouridation of the water supply does not do away with the necessity for dental education and for dental care, and these elements of the program will continue to require reappraisal and modification."

Dr. Russell stressed the importance of the contributions made by public health dentists to basic knowledge and methods of control of oral diseases, even though "research per se" is not their primary duty.

Most difficult in evaluating research finding, according to Dr. Russell, is for the dentist and the statistician to evaluate someone else's findings, using only data found in a published report. The dentist must make the decision on the value of any measures suggested by such a report, basing such a decision on contemporary opinions, published analyses by dependable groups, or on direct clinical tests which he himself may make.

An adequate study, said Dr. Russell, should include (1) a concise but exact description of methods or criteria; (2) evidence that adequate numbers have been studied, although a small-sample study may be highly conclusive; (3) strict and direct control; (4) simple, clear logic; and (5) conclusions fully supported by evidence. It is best to withhold judgment on a single study

until it has been duplicated and the conclusions confirmed at least once.

Dr. Russell called attention to a point which the statistician should recognize at a glance—the *person* is the unit of sampling in a clinical dental study and not the number of teeth being studied.

RECORD SYSTEMS

Medical Students Taught Certification

The "minimum effective dose" (m. e. d.) for the teaching of death certification to medical students is "believed to be a continuance program of repeated indoctrination, experience, study, and discussion that builds desired appreciations and habits step by step as the student's medical education progresses," the American Association of Registration Executives and the statistics section of the Western Branch were told by Adolph Weinrill, M. D., and Carl E. Hopkins, Ph. D., of the University of Oregon Medical School.

Teaching of future physicians should produce, they felt, active appreciation of the need for data, of the registration and vital statistics system, of the common sources of error and how to prevent them, and of the physician's key role in the system.

Drs. Weinrill and Hopkins said they tried "one-shot" lectures on

"the why's and how's of medical certification" and rejected them as ineffective. They said their m. e. d. was effective "only if due attention is paid to the basic elements of the learning process." Whenever possible, the necessary verbalizations need to be accompanied by exercise, on the part of the student, of the primary senses and motor activities. The sequence of drive-stimulus-response-reward must be repeated over and over in an expanding context of collateral medical knowledge, they found, emphasizing that "the entire process seems to work best in a comfortable, nonauthoritarian climate of feeling."

State-Local Project

Now under development in California is a long-range plan that will transform records, reports, and reporting procedures from a "millstone around the neck" of administrators into an efficient, useful tool in program planning, operation, and evaluation, the statistics section heard from Paul W. Shipley, B. S., chief of the bureau of records and statistics of the California State Department of Public Health.

He reported that for the first time in the State the personnel responsible for program planning and operation of both the State and local health departments have pooled their resources in an orderly approach to solving "this most complex problem."

Environmental Health

WATER AND SEWAGE

17 Million Served by Individual Sewage Units

Only 40 percent of the 4,400,000 individual household sewage disposal systems in the United States were installed under organized State or local health agency control, V. G. MacKenzie, B. S., officer in charge, Environmental Health Center, Pub-

lic Health Service, reported to the engineering section. These systems serve 17 million persons, compared to 75 million served by public sewer systems. Trends indicate the importance of individual systems will not be reduced, he said. Forty percent of the homes being built with Federal mortgage insurance assistance depend upon individual systems for sewage disposal.

Reporting on studies of septic tank performance characteristics, Mr.

MacKenzie emphasized factors of capacity, shape, compartmentation, depth, inlet and outlet arrangements, and other factors affecting operation. The removal of suspended solids was taken as the criterion of tank performance. He also stressed the variations in composition and volume of household wastes as a basic consideration in design standards.

Concerning the effect of household detergent use on soil absorption

systems, additions of detergent and soap, respectively, to tank effluents indicated no differences in clogging tendencies, Mr. MacKenzie said. Similar studies with grease-soap and grease-detergent tap water suspensions showed greater clogging for the soap. Tests with wash waters from a home washer, using soap and detergent alternately, showed no differences in clogging rates when applied to soil cores. Both soap and detergent washer wastes clogged soil more rapidly than normal septic tank effluent.

Mr. MacKenzie said that the septic tank is not a complete disposal system but a unit of a process for disposal of waste liquid into the soil—a medium that is sensitive to the heavy waste loads placed on it and susceptible to damage from abnormal changes in those wastes. This and all factual information concerning septic tanks should be considered in the design, operation, and servicing of each individual tank installation, he concluded.

The Membrane Filter

A method for bacteriological analysis of water which promises a substantial reduction in time, material, equipment, labor, and space, and yet will, in all likelihood, be more certain and precise than present methods, was described to the engineering section by Harold F. Clark, M. A., and Paul W. Kabler, M. D., bacteriologists from the Environmental Health Center, Cincinnati, of the Public Health Service.

The apparatus consists of a funnel and receptacle and is made of stainless steel. The sterile membrane is placed on a porous plate in the receptacle, and the funnel is clamped over it. Removal of the bacteria is effected by passing the sample through the funnel. The method permits use of large quantities of sample, 500 ml. or more, they stated.

Dr. Alexander Goetz made the membrane filter apparatus, and it was supplied through the Army Chemical Corps. The filter is prepared from a cellulose derivative and will quantitatively remove bac-

teria from water samples. Bacterial counts by the membrane filter technique require filtration of a representative amount of sample, choice of a suitable medium, incubation, and counting the colonies, according to Clark and Kabler.

They reported that coliform determinations require about 18 hours instead of 3 or 4 days needed by present procedures. Details of this procedure were described in *Public Health Reports* for July 27, 1951.

Differential Media

The membrane filter method for the culture and identification of bac-

teria is unique in that it enables the bacteriologist to transfer growing organisms to two or more enrichment and/or differential media at any period in their growth cycle, Dr. Kabler and Mr. Clark reported in another paper before the laboratory section.

Each organism provided with suitable nutrients will produce a visible colony. The incubation time and temperature depend on the species of bacteria to be grown and the medium used. All components of the medium used with the membrane filter technique must be in solution. The formulae of most

The Goetz membrane filter apparatus is demonstrated by Harold F. Clark, bacteriologist of the Environmental Health Center, who has developed some of its uses in sanitary bacteriology. The filter was on display as part of the Public Health Service exhibit-demonstration at San Francisco. The filter technique was described in *Public Health Reports* for July 27, 1951.

media for conventional uses must be modified for best results with the membrane, they stated.

Species Identification

Concomitant with growth of the colonies on the membrane, the problem of group and/or species identification must be considered. Efforts have been made to develop differential media which produce a characteristic color change in or around the colony, inhibit unwanted groups or species, and exhibit both inhibition and characteristic color reaction, they said.

The results of experiments with seven media for growth of several species of bacteria were described and evaluated by Dr. Kabler and Mr. Clark. A modified Endo medium was found very good for the demonstration and enumeration of coliform organisms. Bismuth sulfite was excellent for growing *Salmonella typhosa*. For other *Salmonella*, preliminary enrichment on tetrathionate broth followed by incubation on brilliant green (Kaufmann) gave high recovery rates.

Sewage Water Reclaimed

A 2-year sewage reclamation study by the University of California sanitary engineering research project indicates that although no satisfactory basis for the design of sewage spreading areas has been determined, it is possible to reclaim water from sewage by spreading, the engineering section was told by project members, Arnold E. Greenberg, S. M., and Harold B. Gotaas, Sc. D., research engineer and director.

Planned reclamation is a comparatively recent development, designed specifically to produce a usable water, and is receiving serious consideration in water shortage areas. In their study of sewage effluent spreading on uncultivated land, Mr. Greenberg and Dr. Gotaas concluded that a bacteriologically safe water can be produced from a good sewage plant effluent and that a chemically satisfactory water can be produced

from the final effluent of a plant treating domestic sewage.

A percolation rate of 0.1 foot per day can be expected from spreading a final sewage plant effluent on Hanford fine sandy loam. Resting and spreading of the spreading basin will maintain maximum percolation rates. Mosquitoes will create a nuisance requiring control, they said, and control of algae odors may also be necessary.

Water Pollution Control

A discussion of the comprehensive and sweeping changes in State laws for the control of water pollution enacted by the 1949 California Legislature, creating a State and nine regional water pollution control boards, was presented to the engineering section and National Association of Sanitarians by Vinton W. Bacon, executive officer of the California State Water Pollution Control Board.

The new legislation establishes by definition the concepts of "contamination," "pollution," and "nuisance." The authority of the State and local departments of public health is restricted to cases involving contamination. Abatement of pollution and nuisance rests with the State and regional water pollution control boards.

Control of waste discharges is exercised through treatment-plant effluent or receiving-stream quality requirements. This abolishes the former "permit" system which required advance review and approval of plans and specifications for proposed waste treatment and disposal facilities.

Coordination of water pollution control activities of all State, regional, and local agencies is a prime objective of the new legislation, continued Mr. Bacon. Pollution control is decentralized and placed on the regional level, with regional policies being established by a five-member board appointed from within the region. Control is based on a case-by-case study and analysis of water uses rather than by a fixed rule, Mr. Bacon said.

SANITATION

Food Handler Training Pays Large Dividends

Information thus far accumulated in a number of California communities in a survey by the State Department of Public Health indicates that food-handler training pays substantial dividends, Ralph L. Tarbett, B. C. E., associate sanitary engineer of the department, told the sanitation section of the Western APHA Branch.

Mr. Tarbett said that, although positive conclusions cannot be made at present, there is evidence of dividends in improved restaurant sanitation, better relations between the restaurant industry and local health departments, and increased public support for the program.

The State Department of Public Health began the survey of the effect of food-handler training at the request of the 1950 California Conference of Local Health Officers, which had gone on record as favoring education and inspection as parts of a food sanitation program. Consultants from the American Public Health Association, United States Public Health Service, and the University of California School of Public Health aided in planning the methods, forms, and techniques used in the survey, he said.

Much of the criticism of health departments regarding food sanitation is the lack of uniformity in recommended practices and legal interpretations of laws, Mr. Tarbett noted. He felt that these studies, in addition to measuring the value of food handler training courses, will tend to combat this criticism and develop closer relationships between the State and local health departments.

Local Sanitation

Other sanitation activities at State and local levels were discussed at meetings of the Conferences of State Sanitary Engineers and Municipal Public Health Engineers. John M. Helper, C. E., State sanitary engi-

neer of Michigan, stated that the widely practiced food handler training program is not accepted in Michigan, due to the large turnover of personnel in food handling businesses. He felt that this activity should be critically re-examined as a health department program.

Other speakers stressed that where local sanitation personnel are available, sanitation work can and should be done by them, but there is a considerable job for State health departments in providing sanitation for small communities and rural areas. It was also pointed out that the need for sanitation personnel must be based on environmental units rather than population units.

The engineers' conference also heard a panel discussion of interstate milk shipment program responsibilities. F. L. Woodward, chief, section of environmental sanitation, Minnesota Department of Health, told the joint session that the role of the United States Public Health Service in the program is to rate State survey and laboratory people and to disseminate information and data regarding milk supply ratings. Otherwise, it is a program of the milk producing and receiving States, he said.

Other panel speakers commented on reciprocal milk programs among local health jurisdictions within the States and on different legal and technical aspects of reciprocal milk shipments.

Checking Specifications

Why should sanitation personnel depend upon building departments to do their job for them? Should they not check the sanitation items in building plans and specifications, rather than depend upon someone who may be less qualified or less interested in those items? These were questions presented to the engineering section and the National Association of Sanitarians by Frank A. Gohr, M. P. H., and Jordan F. Hiratzka, B. S., sanitarians, Department of Sanitation and Public Health, student health service, University of California at Berkeley.

In stressing the desirability of using a check list of sanitation items for reviewing building plans, they pointed out that of 44 local health departments queried in California, less than one-third used any form of a check list. While many of this third used applicable codes, such usage is unsatisfactory since they include much material extraneous to sanitation, thereby requiring numerous books and pamphlets to do a satisfactory checking job. Also, codes and ordinances in general usually contain such nebulous terms as "adequate," "sufficient," "satisfactory," etc., they continued. Is it not better, they asked, to incorporate sanitation items from these and other sources into a single volume, replacing vague terms with definite concrete standards?

Such a check list and manual has been used since early 1951 by the Department of Sanitation and Public Health at the University of California. From past experiences and national and local codes, ordinances, standards, and practices, the department has assembled into one volume pertinent, specific items relative to sanitation and public health in building construction, renovation, and repairs.

The check list and manual is sufficiently broad and versatile to include diverse phases and different categories of construction embodied in medical, laboratory, and classroom buildings and has won unanimous approval of key building and construction personnel at the university they said.

MANPOWER

5,000 Engineers Now in Public Health Activity

There are an estimated 5,000 engineers in the United States participating in public health activities, Francis B. Elder, M. S. P. H., engineering associate, APHA, reported to the engineering section. Data assembled by the section from 1949 through 1950 revealed that the average of the continental United States

is 3.2 sanitary engineers per 100,000 population. The range in States is from 1.4 engineers per 100,000 in Kentucky to 7.7 in the District of Columbia. Mr. Elder noted that Alaska has a ratio of 5.4 and Puerto Rico 0.5 engineer per 100,000.

Public health agencies ranked highest in employment of sanitary engineers, with 1,365, or 28 percent of the total. Of this group, 651 are employed by State agencies; 290 by municipal; 263 by Federal; and 82 by special districts. Consulting offices employ 1,239, or 25 percent of the total, and various public works, 868, or 18 percent.

Mr. Elder said that less than 15 percent of the engineers are not practicing sanitary engineers. Over half give more than 75 percent of their time to such duties. Sixteen percent devote half to three-quarters of their time, and 17 percent devote less than 50 percent of their time to sanitary engineering activities.

Thirty-two percent of the engineers are in the age group 35-44, said Mr. Elder. There were only 115 younger than 25 years, but 622 older than 60. Sixteen years is the extent of education for 43 percent of the engineers, while 20 percent have had 18 or more years. Only 4.5 percent have 12 years or less of education, of whom 79 percent were 45 years or more old.

Mr. Elder said that 188, or 11 percent, of the sanitary engineers are in the regular service of one of the military departments of the Public Health Service and 1,681, or approximately one-third, hold reserve commissions or are on active duty with those establishments.

Half of Undergraduates Stay

Approximately 51 percent of the undergraduate sanitary engineering students and 77 percent of those who take graduate work in sanitary engineering follow the profession for which they were educated, Arthur P. Miller, C. E., Division of Engineering Resources, Public Health Service, reported to the engineering section. This conclusion is derived

from past and present studies conducted by Mr. Miller and Walter A. Lyon, senior assistant sanitary engineer (R).

Mr. Miller presented data from these studies in discussing the flow of men into the sanitary engineering profession, the degree to which they are prepared to carry out their work, and their numbers and distribution. He pointed out that, with few exceptions, most sanitary engineering undergraduates have available to them only a modified civil engineering curriculum. Also, he continued, there are wide variations of opinion among institutions offering undergraduate training as to the scope and content of the curriculum. He said the number of such institutions has risen from 21 in 1938 to 40 in 1950, and 57 universities now offer graduate education in sanitary engineering.

From 1951 through 1954, 419 sanitary engineering graduates are expected to be available for employment, but Mr. Miller estimated that only 210 would enter and remain in the profession. Sanitary engineering appears to have arrived at the time when losses due to retirement and death will be increasingly felt, he said.

The Public Health School

If schools of public health are to help in the manpower crisis, the field of public health must be so redefined that it will have an appeal based on the professional background and aptitude of those who are trained in the professions, Henry F. Vaughan, Dr. P. H., Dean of the University of Michigan's school of public health, emphasized to the engineering section.

The responsibility of recruitment should be shared alike by the school of public health and the employing agencies, said Dr. Vaughan. To make the maximum use of the shrinking personnel reservoir we must evaluate the various jobs in terms of the skills required. For example, the job of the physician must be so defined that he can be relieved of administrative details which can be carried out by lay per-

sonnel. The physician should be conserved for medical work; the engineer for engineering activities, he said. This would make a public health career more attractive to the prospective student.

Dr. Vaughan stressed that the object of schools of public health is to train those now required and to be required by the health agencies. Since the practice of public health is constantly changing, the training job is not an easy one, he said. Training must be comprehensive and must deal with the community as a whole even though certain public health functions may be the responsibilities of other than public health departments.

The emergency type of health service has been superseded by a program emphasizing health education, Dr. Vaughan continued. Budgets, personnel management, recruitment, merit systems and understanding community social needs, control of the chronic diseases, and a program of gerontology have replaced the problems of the exotic diseases. Complexities of stream pollution, sanitation, and atomic, chemical, and bacteriological warfare are now facing us, he said.

To meet these changing situations, said Dr. Vaughan, the school of public health must provide additional training for professional people with diversified backgrounds essential to the completeness of the public health team; develop new types of personnel to meet the needs of general service; train a few specialists; and provide continued education for those who are already employed in the health services.

The Engineering School

The role of the engineering school in meeting the manpower crisis was discussed at the engineering section meeting by S. T. Harding, consulting engineer, Burbank, Calif. The development of special engineering courses to meet defense needs should be withheld until these needs are properly defined by adequate authority, declared Mr. Harding. He stressed that while the current manpower crisis is immediate, it should

be met with the minimum disturbance of the long-time objectives of engineering education.

Whenever specialized training or accelerated programs are necessary to the defense effort, the engineering colleges are equipped to meet these needs in plant and faculty and have experience in the last war to serve as a guide. Until then, said Mr. Harding, they can serve best by continuing their standard undergraduate training.

He felt that in encouraging students to enroll in engineering courses, short-time conditions should not be stressed except as a matter of emergencies and patriotic service. The prospects for an engineering career should be presented for average economic conditions rather than for depressions or booms, he said.

Some accelerations of engineering courses may be practicable, but compressing the 4-year curriculum into three unbroken years of study was generally unsuccessful in the last war, Mr. Harding continued, because students can become mentally as well as physically stale. As an alternative, he proposed the elimination of liberal arts courses and the segregation of studies into specialties.

AIR POLLUTION

20,000 To Be Studied In Detroit-Windsor

A comprehensive study of the effects of air pollution on the health of citizens in the Detroit-Windsor, Ont., area is now being planned by The International Joint Commission in Controlling Air Pollution, the engineering and industrial hygiene sections were told by J. R. Menzies, chief, Public Health Engineering Division, Department of National Health and Welfare, Ottawa, Canada. This is probably the first occasion when the technical and scientific resources of two nations have been combined in a joint effort to determine the effects of air pollution on public health, he reported.

The tentative proposal is to include 5,000 family units in Detroit and Windsor, which will provide

morbidity data on approximately 20,000 persons. The family units will be divided into six groups based on their socioeconomic status and the air pollution intensity to which they are subjected. Mr. Menzies said special attention will be directed to diseases of the respiratory system.

Much of the engineering data to be used in conducting this study has been collected by the commission since 1949, when it began an investigation seeking means of controlling and reducing the amount of smoke, soot, and fly ash produced by Detroit River vessels. The investigation was then broadened to include the emission of objectionable industrial gases and particulate matter in the highly industrialized area.

The Engineering Approach

New techniques and methods for measurements and removal of air contaminants were described to the engineering and industrial hygiene sections by Hamnett P. Munger, Ph. D., in charge of air pollution research, Battelle Memorial Research, Columbus, Ohio. Dr. Munger described a directional dirt-fall collector which he felt to be of particular value in highly industrialized areas. With the use of this collector it should be possible to determine the direction from which the major contaminant comes, he said.

A low-velocity wind tunnel, condensation nuclei recorder, miniature Venturi scrubber, and other equipment are now being perfected to furnish specific information concerning air contaminants, continued Dr. Munger. He also presented newer developments in the means of sampling and analyzing aerosols.

In stressing the role of meteorology and topography in the accumulation of contaminants in industrial areas, Dr. Munger described kite-balloon methods for measuring meteorological parameters and topographic effects. In applying these techniques to industrial problems, he said, each situation must be studied, plant by plant, to obtain the most economical method for reducing air contamination.

Smog Diminished

The Los Angeles smog problem is diminishing, Gordon P. Larson, director of the Los Angeles County Air Pollution Control District, reported to the engineering and industrial hygiene section. He said that due to the control district's efforts air pollution from common visible sources is being controlled, with the result of a decreasing number of intense smog days, improvement in visibility conditions, and public recognition of a noticeable improvement in general atmospheric conditions.

Mr. Larson said that some groups maintain that medical research is the answer to the air pollution problem and argue that controls should not be instituted until the effects on health have been determined for each pollutant. This would involve waiting many years until expensive and time-consuming studies can be completed, he continued, and the public's alarm about smog requires that some air pollution action be

taken now. The application of control techniques is the most that anyone can do at present, he said.

In the past 3 years Los Angeles area industry has expended seven and a half million dollars to control pollutants at the source, he continued. The metals industry is now collecting 85-99 percent of its metallurgical fumes, and the dust producers, which include processes such as milling and grinding, have collection efficiencies well above 95 percent.

Mr. Larson said the requirements for the collection of dusts and fumes were specified after a detailed study of contributing sources, economic factors, and available engineering techniques. A limit for sulfur dioxide emitted by chemical plants and refineries has eliminated local crop damage from this gas, he said, adding that odor problems from rendering plants and fertilizer, paint, and canning industries have been successfully resolved in every instance.

Smoke particles from commercial and industrial plants have been reduced by 60 percent, he continued, but public rubbish burning still presents a problem which is now being attacked. Mr. Larson felt that successful control of smoke, dust, fumes, and odors indicates that similar results can be achieved on other pollutants as they are discovered.

Strong Laws Needed

Air pollution control laws must be made strong in both coverage and penalties, even when conciliatory and educational measures are contemplated in their enforcement, the Committee on Air Hygiene reported to the engineering and industrial hygiene sections. Chairman H. A. Whittaker said that public educational measures are of real value as propaganda mediums but are of little use if the law governing air pollution is weak. He felt that the primary accomplishment of educational measures is to keep the public aware of the existence of the law.

—Micro-photo from air pollution district, county of Los Angeles.

The smog particles seen here under the electron microscope were collected in Los Angeles County from smoggy air with a micro-impactor which impinges the tiny particles on glass slides. It is believed that these particles are largely responsible for reducing visibility. Their size is in the order of $1/25,000$ of an inch in diameter. They appear to be comprised of both liquid and solid particles. Magnification 2700 X.

**Uterine Cancer:
The Problem of Early Diagnosis**

16-mm., sound, color, 21 minutes. 1951.

Audience: Physicians, especially general practitioners; medical students.

Available:

Loan—State and local Health Departments and State Cancer Societies.

Purchase—Apply to American Cancer Society, Inc., 47 Beaver Street, New York 4, N. Y.

This is the fourth in a series of films sponsored jointly by the American Cancer Society and the National Cancer Institute of the Public Health Service, Federal Security Agency. The film reviews the commonest forms of cancer and stresses the importance of the general practitioner in discovering the disease early.

While it discusses uterine cancers in general, the film concentrates on the most prevalent form, carcinoma of the cervix. Employing animated diagrams, charts, and live action (including several views through the cervical speculum), the film brings out the effect of early detection of malignancies on 5-year survival rates. Techniques of detection are given the most attention. The one which is recommended as a standard office procedure for the practitioner is the vaginal smear. The interpretation of such material, it is stressed, should be entrusted only to trained pathologists.

Several cases of cervical pathol-

Dr. George Papanicolaou instructs a class on the highly specialized technique of interpreting vaginal smears.

Method of obtaining cervical cells for cytological study, using an ordinary tongue blade, split lengthwise.

The essential equipment with which the general practitioner can perform the safe and simple procedure as a part of his office routine.

ogy are reviewed to show how the vaginal smear is used in actual practice to detect and in some cases to help rule out malignancy. The point is made that all cervical cancers may start as tumors in situ, and that such tumors—in most cases detectable by the methods outlined—may well be 100-percent curable. In this respect, the film is the strongest of the series so far, in stressing the philosophy that pervades them all: early suspicion and accurate diagnosis make possible the

most effective treatment of cancer.

Other films in this series now completed are: Cancer; the Problem of Early Diagnosis, 1948; Breast Cancer; The Problem of Early Diagnosis, 1949; Gastrointestinal Cancer; The Problem of Early Diagnosis, 1950.

Fluoridation Story

16-mm., sound, color, 3½ minutes. 1951.

Audience: General public.

Available:

Loan—State Departments of Health, Regional Offices of Federal Security Agency.

Purchase—Terms to be arranged.

This film short presents quickly and simply the advantages of adding fluoride to a community's water supply. Its message is confined to practical facts about fluoridation: kinds of fluoride compounds used, low cost, lack of harmful effects, and concrete benefits in terms of a 65-percent reduction in tooth decay, better health, and substantial savings in dental bills. The effect of animation is achieved in the film by liberal camera movement and the use of "pop-ons." The film is equally suitable as a motion picture trailer, as a filler for 16-mm. film programs, as a television spot, and in exhibits with continuous projectors.

65 percent less tooth decay . . .

. . . For about 10 cents a year per person

Comparison of relative incidence of and mortality from major types of uterine cancer.

The Health Department's Dilemma

—Definitions and Functions—

By JOSEPH W. MOUNTIN, M.D.

From time to time, the public health profession, and particularly the health department, finds it necessary to redefine its field. The need for a new definition seems to strike us when there are substantial changes in problems and especially when major readjustments are in the making. This mid-century point is obviously one of those times, because many of the old problems have been resolved and because new opportunities for advancing human health are opening up constantly.

A definition, it may be mentioned at the outset, may be philosophical or broadly descriptive; or it may tend to fix boundaries. In the sense, however, that definitions help us clarify and delimit our responsibilities, they have much more than an academic or abstract interest for public health workers. They are the basic tools in determining the direction and scope and value to society of health programs. Certainly those of us who are administering a health program can appreciate the need for delineating functions and responsibilities. Wisely conceived and properly interpreted, a definition can serve a very useful purpose. But if a definition merely serves to restrict health departments, that is, if it is used to shut them

out of current problems and activities, it can also be stultifying.

This brings us to a fundamental question: Can we ever hope to arrive at a definition that will give us a focus of operations and yet not be completely limiting? Many health workers know from their own experience how the act of setting boundaries often serves as an obstacle to the progressive development of services. Although the way out of this dilemma may not be readily discernible, we should be able to recognize its complexity and the reasons for its existence.

Dynamics of Public Health

The content and scope of health services, like society itself, undergo constant change. As old problems are solved or fade into minor significance, new ones or those unappreciated in the past arise to take their place. If we attempt to arrive at a frame of reference that will be meaningful in terms of specific health department responsibilities, it becomes obvious that no single concept can answer all our needs. It is almost impossible, in other words, to arrive at a definition that will be enduring and universal. The concepts that were appropriate some years ago do not—nor can they be expected to—take cognizance of current health problems and responsibilities.

On the other hand, an accurate description of public health in this country today would hardly be valid for vast areas of the world. In many parts of the world the absence of simple

Dr. Mountin is chief of the Bureau of State Services, Public Health Service. This article is based on a paper read at the fifth annual meeting of the Massachusetts Public Health Conference and the New England Health Institute in Amherst, Mass., on June 15, 1951.

personal and community hygiene underlies most of the health problems, and such diseases as malaria, intestinal disorders, and tuberculosis account for a very high proportion of deaths and disability. It would be necessary to go back, therefore, as much as a century in our own history to seek a suitable content for health programs in underprivileged parts of the globe today.

Public Health in Retrospect

Certainly up to the turn of the century our measures for meeting health needs even in this country, although realistic and effective, were little more than introductory. If public health had followed the comprehensive approach embodied in the Shattuck report (1), we might, from the very start, have moved forward on a much broader front than sanitation and infectious disease control. For example, this is what public health meant to Shattuck and his associates over 100 years ago: "The condition of perfect public health requires such laws and regulations, as will secure to man associated in society, the same sanitary enjoyments that he would have as an isolated individual; and as will protect him from injury from any influences connected with his locality, his dwelling house, his occupation, or those of his associates and neighbors, or from any other social causes." The emphasis on man as a social being and as a product of a social environment is amazingly modern.

But the dramatic effects of water purification and sewage disposal on human health were too compelling to be ignored. As a result, public health became set on the road it was to follow for the next 50 years and more—essentially the sanitation of the physical environment.

This is not to deny that environmental sanitation was an indispensable first step. The public health pioneers were fully attuned to the realities of their day. It was the slums and dirt, the overcrowded and inadequately safeguarded living conditions, and the poorly disposed, disease-bearing sewage and wastes that constituted the greatest menace to health in those days. The early leaders may have been vague as to etiology and imprecise as to control techniques. But they were crystal clear about

the conditions they wanted combated through organized social action. And it was in response to those needs that organized public health programs developed and that professional responsibilities began to be recognized.

But the needs and the acquisition of new knowledge soon outgrew the original concepts. Public health began to acquire a systematized body of knowledge and experience that enabled it to shift its attention to preventive personal medicine and to tackle environmental hazards with increasing precision. The first decades of this century saw the beginnings of this new type of public health campaign, with its attention to the childhood ailments and the concerted attacks on the infectious diseases. The rapid development of bacteriology had brought many new techniques which enabled us to go beyond quarantine and disinfection, for a long time the principal measures for limiting the spread of contagion. Immunization against a wide range of diseases became possible and specific serums gave us our first effective therapy against many illnesses. The early decades of this century also saw the beginnings of the science of nutrition, which changed the course of control for several diseases. Finally, they were characterized by the development of considerable specialization, both in professional disciplines and in health services.

In these decades public health agencies exerted strong leadership by stimulating the new programs and using the new techniques. The efforts to prevent and control epidemics, to curb such diseases as diphtheria, smallpox, and typhoid fever met a real, demonstrated need of the people. And it was in answer to this need that modern local health organizations began to grow.

It was, in fact, out of this period that our current ideas of public health services evolved—concepts that included a "categorical" approach to disease, specific control techniques, and specialized, even compartmentalized services. As another result, public health workers began to give thought to the organizational structure for conveying services to the people. We began, thus, to acquire rather firm ideas about "basic" responsibilities and services, and about minimum standards of personnel and organization. And these concepts, once highly appropriate,

still cling to our consciousness in the face of changing conditions and altered needs.

New Needs and Directions

That the needs and the problems have changed substantially even within the last decade does not, I am sure, require much documentation. Many of the once most-feared infectious diseases are now negligible problems. The rapid development of antibiotic therapy has reduced the importance of most of those that remain to minor clinical entities. Moreover, the eradication of some transmissible diseases by mass therapy now looms as a distinct possibility. Syphilis is a case in point. In addition, public understanding about personal hygiene, sanitation, and the control of communicable diseases has progressed hand in hand with the improvements in knowledge and methodology.

Nevertheless, there are today many areas of unfinished business in public health—and even more important, many which are not yet started. The factors which have given rise to them are, of course, well known. The general aging of the population, the increase in chronic diseases, the problems associated with our complex industrial and social environment, all combine to create a new setting for public health.

In addition, a new approach to health itself is being fostered by professional groups as well as in the popular mind. Health is now being thought of, not in terms of disease or mortality figures, but in a positive way, in terms of physical fitness, mental and emotional adjustment, and social satisfaction and usefulness. In other words, health is no longer considered solely as an end, but also as a means. The public health responsibility cannot be considered liquidated once we have reduced infant mortality to the vanishing point, or conquered malaria or syphilis, or even cancer and heart disease. It must be geared to promoting ever higher standards of human efficiency and satisfaction.

As an important corollary of this approach, public health workers are obliged to take a new look at the origins of social pathology. Health problems cannot be isolated from the environment—both physical and social—in which they exist. Such factors as the individual's job, his

family life, his housing, his recreation must all be assayed for their impact on health and disease. In other words, we must now not only put emphasis on the individual and his needs, but also consider him in relation to his whole complex socioeconomic environment.

This brief review of the major trends in the historical development of public health in this country suggests a conclusion that is already well known, that public health is dynamic and progressive. It develops at different rates of speed, depending upon differences in time, place, and problem. And, up to the present at least, the solution of one problem has only sharpened our awareness of needs in new or neglected areas.

Limitation by Definition

The progressive nature of public health makes any restricted definition of the functions and responsibilities of health departments difficult. More than that—there is a real danger in attempting to narrow down a moving and growing thing. To tie public health to the concepts that answered our needs 50 years ago, or even a decade ago, can only hamstring our contribution to society in the future.

Consider the results if the public health profession had fixed or solidified its responsibilities during any of the earlier periods just noted. Perhaps we would still be concentrating on gross environmental sanitation or, if our program became static at a later period, we would still be limited to placarding and fumigating. Even if our responsibilities had crystallized as much as a decade ago, we would have practically no cancer control or mental health programs today. These and many other recognized activities would be ruled out if we truly limited public health programs to the so-called basic six—the minimum functions which have been suggested for local health departments; nor would there be any room for an aging or a hygiene-of-housing program in the future.

In allowing itself to be guided by a limited definition, public health may fall into the error of substituting the symbol for the job, of mistaking the contrived concept for the actual responsibilities that the people want met. This becomes the start of a descent. The next step,

the one that is far more dangerous, is to live down to the artificial symbol instead of living up to the actual job.

If a public organization or agency is not alert to changing needs, if it grows insensitive to the desires of the people, it becomes rigid and actually falls behind the times. It not only tends to lose popular support but fails to attract the kinds of professional personnel it needs to carry on its programs. Moreover, a narrow outlook constitutes an open invitation for new programs to spring up under other auspices, which may be less well equipped in terms of professional competence and technical experience.

For example, how many health programs have gone by default to other governmental agencies because the health department was not ready to modify or redirect its efforts? A 1950 sample survey of the distribution of State health services (2) reveals that in at least one State, 23 State agencies are administering important health functions and that in no State are these activities administered by less than nine. This extreme dispersion is even more pronounced when we examine some of the newer programs individually. For example, in a single State as many as seven different agencies are engaged in some kind of accident prevention programs. Similar situations exist in such fields as water pollution control, hospital planning and construction, mental health, and the administration of medical care programs.

I am not suggesting that all public health services need be the exclusive province of the official health department. Far from it. In our complex civilization, many organizations—voluntary as well as official—have an important role to play. But I think the figures are significant in that they reveal the health department's reluctance to sponsor new services or to accept new areas of interest, despite the fact that these services fill a demonstrable void on the local scene.

A Modern Concept of Services

The question may still be asked: Are there any guidelines which we can use in determining current services and responsibilities of health departments and at the same time avoid being restrictive? The answer is "yes," provided the

guidelines are kept flexible and leave room for future modification of program content. In its recent revision of the functions and responsibilities of the local health department, the American Public Health Association (3) noted that the rapid development of health services has caused the definitions of local health services and responsibilities "based on limited categories of activity" to become "quickly outdated." They recommended instead that "optimal" responsibilities be identified and that health department services be expressed in general terms. Seven general types of service are listed, namely, the recording and analysis of health data, health education and information, supervision and regulation, provision of direct environmental health services, administration of personal health services, operation of health facilities, and coordination of activities and resources.

On looking at this list, one's first impulse is to say that seven services have now been substituted for six. But the differences are far more important than the addition of a new responsibility. The earlier statements identified specific programs or functions whereas the new listing indicates general areas of service, under which one or several programs may be included. The term "basic" or "essential" may imply that other services are little more than frills; and as a result minimum functions soon become the major or the sole activities of the health department. The broader approach opens up the road for a thrust in any direction, depending on where the greatest need exists.

The transition from a concept of "basic" services to one of "optimal" services is an extremely important one. It raises our sights far above the routine and static activities that still characterize too many health departments. It means a recognition of the realities of the day. And it implies the readiness, the willingness, and the competence to step in and take some positive action wherever a health problem exists and is being neglected.

On the other hand, this approach is not one of unlimited expansionism. It is not a matter of simply adding one job on top of another until we amass a long string of impressive responsibilities. At least two factors should militate against such a mushroom type of growth.

The first is that public health is and should continue to be subject to social controls which will effectively prescribe our areas of responsibility. It is one thing to say that public health should not be impeded by definitions that are designedly restrictive. It is another to recognize that public health must adapt itself to the will of the community. Such practical matters as budget and fiscal considerations—sometimes looked on as the bane of our existence—actually provide the opportunity for considered review of our activities. On these occasions, too, representatives of the people reflect the community's needs, problems, and desires for service. In a democratic society, we can rely on social controls for the guidance and advancement of public programs, but only if these controls are allowed to operate freely.

The second factor involves the recognition by public health agencies of an important obligation. They owe it to society to modify or reduce those activities which may be marked as finished business or as business that offers only limited returns on the investment. For example, many commercial organizations as well as consumer groups are now deeply aware of health and sanitation measures and put them into daily practice. Restaurants and food establishments are beginning to undertake programs to supervise their own sanitation. The housewife insists on a clean butcher shop and grocery store. Because this is so, health department staffs no longer need conduct the same kinds of detailed inspection and regulatory programs that were formerly the rule.

Food-borne outbreaks of disease must undoubtedly be guarded against vigorously. In fact, a great many such outbreaks still occur each year. But health departments might prevent these occurrences by a program of general education and standard setting and by the training of food handlers, supplemented by judicious law enforcement. Particularly where they are operating within a limited budget, they might rely on spot checks and on more precise information about outbreaks now taking place rather than on the general purpose inspection. In such a manner, they might meet the problem more effectively and at less cost and, by the same token, make more time and money available for other activities. Sanitarians could

devote more of their energies to contemporary problems in food sanitation and to other new fields, where their experience and training can be put to good use. They might, for example, be working on such broad social problems as community planning, housing, control of air pollution, and accident prevention.

Somewhat the same situation holds true for the programs designed to improve individual and family health. Many of the time-consuming activities involved in controlling some of the infectious diseases may be modified to a holding type of operation—that is, maintaining vigilance against localized outbreaks of disease. On the other hand health departments must turn more attention to other types of personal health services.

Opportunities Unlimited

Preventive health work no longer means solely safeguarding the physical environment or curbing the spread of infection. Today it has a personal connotation and, even more, it means preventing the complications of disease or the further deterioration of one who already has a disease or disability. In the words of the official APHA statement (3): "Because of the marked changes in the age distribution of the population and in the spectrum of our health problems, the theory and practice of public health has expanded to include not only prevention of the onset of illness, but also prevention of the progress of disease, of associated complication, and of disability and death."

Perhaps because there are relatively few primary preventive measures against the chronic impairments, the role of the health department in this field has not yet been clearly established. There are, however, many ways in which the actual or potential resources of the health agency may be utilized. These vary all the way from providing auxiliary services for physicians in private practice to operating the facilities which may be established under public auspices for general or specialized care.

Medical care is also beginning to exhibit many of the elements which are identifiable with a general health service. This is so partly because of the increased effectiveness of therapeutic measures which can be used to combat

certain diseases on a mass basis. The effects of modern therapy on scarlet fever and pneumonia demonstrate graphically how these diseases have been robbed of most of their terrors. There are other, if less dramatic, examples. The new "wonder drugs" not only reduce mortality strikingly but also abort many incipient cases of disease; almost without exception they shorten morbidity and reduce complications. Thus, the health department must be increasingly concerned with the character and availability of medical facilities and services within its geographic area.

Even with our limited knowledge today, much can be done not only to stabilize chronic illness but also to rehabilitate its victims and to help them make necessary adjustments. In light of the social goals of public health, it is our responsibility to play an active part in restoring an individual to his family, his job, and his community. Any recovery or any gain that will make a person in any measure more self-sustaining than he was will mean some degree of improvement, not only for the individual but for society. Even if an individual is rehabilitated from the hospital bed to the wheel chair at home, it represents that much of a social gain in relieving the community of the burden, the expense, and the responsibility of care. If the person is able to return to productive employment, the gains are multiplied many times over.

The Pioneering Spirit

Can health departments assume these new responsibilities without undergoing a major upheaval? I think they can, provided there is a recognition of the need, a reorientation of thinking, and a willingness to tackle the job. The new approach will call for a great deal of administrative and technical pioneering. For example, from our experiences in controlling the diseases of bacterial origin, we are used to dealing with specific, almost rigid, control techniques. For our purposes today, however, we may have to revert once more to the rather general approach reflected in the Shattuck report (1). In such programs as health promotion for older people or mental health, we are dealing with a new kind of social pathology, much of which is still vague and ill-defined.

Thus, we may very well turn to empirical and general methods, at the same time seeking constantly for refinements and for more precise techniques.

The health department can begin preparing for its new responsibilities by surveying the resources and facilities already available in the community and by being ready to adapt or to apply them to health purposes. It must seek and train a wide variety of new competencies and make liberal use of consultants. Cardiologists, psychologists, medical social workers, nutritionists, even economists and sociologists, all have a place in modern health service programs. Although not all of them can or should be employed directly on the staff of every local health department, an interchange of personnel can be made possible through the regionalization of health services. In addition, a progressive program of staff education should be instituted to give professional personnel the broad perspective and well-rounded knowledge they need to conduct the newer health programs. Training should be given not only in the traditional health field but in a variety of related disciplines and particularly in the social and administrative fields.

Moreover, the health agency should call for consultation and advice from people both within and outside the health professions. Engineers and safety consultants as well as epidemiologists, psychiatrists, health educators, and public health nurses have much to contribute to a program in the prevention of home accidents. Social workers, recreational personnel, industrial and labor groups, and housing officials all have to play a part in programs designed to promote the health of older people.

It would seem clear, therefore, that the health department today is only one of a number of agencies—official and nonofficial—which can contribute toward better health. Many of the newer programs must be based on suitable working arrangements between health departments, hospitals, private physicians, and others who actually perform various services.

Other types of administrative reforms and organizational improvements will undoubtedly suggest themselves to health workers once they take the initiative in developing the new programs. What is important to remember is that

a variety of activities are already under way. Excluding health departments by definition merely precludes them from participating in many services where they have much to offer. If health workers remain wedded to concepts unrelated to current needs, health department programs will inevitably be sterile and narrowly restricted. If, however, they not only meet these needs but also keep in mind the broader objectives—improving individual satisfaction and community life—they will be ready to make their maximum contribution to society.

For despite all the health activity that is going on today and despite all the real progress that is being made, there is a greater need than ever for a community organization to spearhead the work and to provide the technical and administrative guidance. That organization should be the focal point of the community's health activity. It should contain the social perspective and the wealth of competency to be

able to perceive the need; and it should have the ability and the courage to take whatever action is necessary.

The people expect the health department to be that organization. They look to it as the community agency which will help find the answers to their pressing health problems. It is to this trust that public health must be truly dedicated.

Parrot Fever Quarantine Revised

Revisions in the Federal quarantine regulations for the foreign importation and interstate shipment of parrots, parakeets, lovebirds, and other psittacine birds have been announced by the Public Health Service.

Changes in the foreign quarantine regulations went into effect December 15, 1951. They remove the 8-month minimum age limit on birds imported for use by zoos and research; reduce from 2 years to 4 months the time birds imported as pets must be in the owner's possession prior to entry into this country, and remove the requirement that imported pet birds must be transported to the owner's residence immediately upon arrival in this country. An added requirement is an affidavit that birds imported as pets are not to be resold and that the owner has brought no other birds into the country during the preceding year.

Changes in the interstate quarantine regulations, which went into effect November 15, 1951, remove all Federal restrictions on shipments of psittacine birds from psittacosis-free areas in the United States, but they prohibit the shipment of the birds from areas where the Public Health Service has determined that psittacosis infection is dangerous to the public health.

None of the changes affect the standing requirement that interstate shipments of psittacine birds must be covered by a permit when it is required by the health department of the State of destination.

Changes in the quarantine regulations followed a Public Health Service study which disclosed that psittacosis is no longer a major public health problem in this country and that the disease is found among birds which do not belong to the psittacine family.

Lead Poisoning in Young Children

By HUNTINGTON WILLIAMS, M.D., EMANUEL KAPLAN, Sc.D.,
CHARLES E. COUCHMAN, and R. R. SAYERS, M.D.

Lead poisoning in young children associated with eating lead-containing paint has been increasingly recognized until it ranks as one of the most common causes of child mortality due to poisoning. However, lead poisoning is not a reportable disease and, therefore, there is a lack of adequate morbidity data (1). The widespread occurrence of lead poisoning throughout the United States and Canada is evident from reports of cases in which eating lead-containing paints was mentioned as the cause of poisoning in infants and young children (2-37). Although 19 different communities are mentioned, most of the cases were from large cities such as Baltimore and Boston, where children's hospitals or local health authorities were especially interested in the problem. During the period 1931-40, the city of Baltimore alone reported 24.3 percent of all the child deaths from lead poisoning reported from the entire United States registration area (1). From January 1, 1931, to June 30, 1951, a total of 293 cases of lead poisoning was reported in Baltimore children. Of these, 83 died (2).

The most common cause of lead poisoning is

apparently the habit of chewing paint from cribs, toys, furniture, woodwork such as window sills, and the eating of painted plaster and fallen paint flakes. The tendency to put things in the mouth, though normal in the first year of life, is considered abnormal if continued into the latter part of infancy, and is referred to as pica, or perverted appetite (6, 30). Pica is the usual forerunner of lead poisoning.

Although pica does not exist on a seasonal basis, a striking number of lead-poisoning cases resulting from this habit occur in the hot summer months. For this, no satisfactory explanation is available, although several investigators have commented on the tendency for lead poisoning to occur in children during the warmer weather (2, 21, 26, 37-40).

Diagnosis, Prognosis, and Sequelae

Unrecognized plumbism, lead poisoning, in children may explain many obscure nervous conditions and convulsions of undetermined etiology (12, 22). Errors have been made in operating on cases presenting symptoms indicating a need for surgery but which were caused by lead intoxication (14, 31).

Lead poisoning is cumulative. Some weeks or months following the continued ingestion of small amounts of lead, symptoms begin to appear. Early symptoms may be only irritability, fretfulness, or disturbed gastrointestinal function characterized by lack of appetite, constipation, vomiting, or cramps. A secondary anemia with resulting pallor is often present. More severe intoxication results in lead en-

Dr. Williams is commissioner of health of the Baltimore City Health Department; Dr. Kaplan is chief of the division of chemistry; Mr. Couchman is director of the bureau of industrial hygiene; and Dr. Sayers, a medical director (retired) of the Public Health Service, is senior medical supervisor of occupational diseases. For several years he was director of the Bureau of Mines, Department of the Interior.

cephalitis due to increased intracranial pressure because of cerebral edema. The acute stages of the disease are manifested in changes in mental state, ataxia, persistent vomiting, muscle weakness or paralysis, delirium, stupor, coma, convulsions, and, not infrequently, death.

Diagnosis involves correlation of a history of paint-eating or pica with the physical findings, laboratory and X-ray data. The importance of eliciting a history of pica cannot be over-emphasized in the early recognition of the disease. Examination of blood smears often shows stippling of the red blood cells. Porphyrinuria is frequently found. The demonstration by roentgenogram of an increased density in the growing ends of the long bones is a cardinal sign of lead poisoning (34). In recent years, the quantitative determination of lead in blood or urine as an index of abnormal lead absorption has proved an invaluable aid in diagnosis (41, 42). Lead poisoning in children differs considerably from the disease in adults. Central nervous system involvement or encephalopathy, rarely seen in adults, is common in children, whereas peripheral neuritis, lead line on the gums, and colic are usually absent.

The prognosis in lead encephalitis in children is poor; the high mortality rate, as well as the incidence of severe, lifelong, residual nervous system injury, has been commented on by many investigators (25). The mental development of even the less severe cases may be seriously impaired (16).

Baltimore Experience

Thomas and Blackfan (3) of the Johns Hopkins Hospital were the first to point out in American pediatric literature the frequency of occurrence of lead encephalopathy in children. Subsequently, studies at the same institution provided pioneer information on the diagnosis (4, 26, 34, 42) and treatment (25, 40) of plumbism in infancy. The Baltimore City Health Department in 1932 began studies of nonindustrial lead poisoning in children in an investigation of cases resulting from the use of storage battery casings for fuel (43). Afterwards, all cases of lead poisoning brought to

the attention of the department were routinely investigated to ascertain the source of the lead.

Blood-Lead Laboratory Service

As an aid in diagnosis, since early in 1935, the bureau of laboratories of the Baltimore City Health Department has maintained a free routine analytical service for the quantitative estimation of lead in the blood of cases of suspected plumbism (41). The dithizone method is used. Especially prepared lead-free blood specimen collection containers known as "blood-lead outfits" are distributed to the local hospitals and physicians in the same manner as outfits regularly provided for specimens in cases of communicable diseases.

Since 1935, almost 3,000 specimens of blood from about 1,800 children have been tested for lead. Increase in this service, as well as the increased number of cases diagnosed during the last 4 years in contrast to the preceding 13 years, is shown in the accompanying table. Undoubtedly, the improved educational activities in lead poisoning prevention in recent years have been a prominent factor in this increase.

Comparison of blood-lead laboratory service tests and cases of lead poisoning in Baltimore children for the periods 1948-51 and 1935-47

Period	Number children given lead test		Diagnosed cases of lead poisoning	
	Total	Average per year	Total	Average per year
1948-51 (4 years)---	1,007	252	166	41
1935-47 (13 years)--	772	59	161	12.4

Field Investigation

Field work, associated with a follow-up of the blood-lead laboratory service, has enabled the Baltimore City Health Department to acquire relatively accurate data concerning the incidence of lead poisoning in the community (1). A report of each blood analysis was forwarded to the bureau of industrial hygiene, which investigated cases in which the blood showed an abnormal absorption of lead. The

Figure 1. Lead poisoning cases reported in Baltimore, according to month of report, 1931-51.

upper limit of normal is considered to be 0.05 to 0.06 mg. percent of lead. Adequate clinical and laboratory data were usually available because nearly all of the children were diagnosed and treated in hospitals.

After learning the medical history, a field worker visited the home of the affected child to obtain pertinent information, particularly concerning exposure to lead. Almost without exception, the cause of poisoning was found to be pica associated with the ingestion of paint. This was confirmed at the time of the home visit by obtaining for analysis a sample of paint scrapings, approximately 0.5 to 1 gm., from surfaces where the child had chewed paint.

Lead Poisoning in Children

Over the past two decades, 347 cases of lead poisoning have been diagnosed in Baltimore

children. These do not include the storage battery cases referred to earlier. Of the 347 cases, 54 have been reported since June 30, 1951. A study of these cases has led to the discovery of interesting patterns in the seasonal incidence of the disease, age and color distribution of the children, and the types of houses involved. It is evident from figure 1 that more cases were reported in July and August than in any other months. There was no significant difference in incidence between sexes. Sixty percent of the cases occurred among children in their second year of life, at teething age, when they have a greater tendency to put things into the mouth. Only 2.3 percent of the cases were in children above 5 years of age.

The annual attack rate for the age segment under 5 years during the period 1931-51 was 7.5 times as high among the Negro population (71 per 100,000) as it was among the white

population (9.5 per 100,000). When the more recent experience of the past 4 years is considered, the attack rates for both white and Negro children as well as the difference between races are significantly elevated above the average experience cited. The high rates among Negro children are a problem of considerable public health significance since 30 percent of Baltimore's preschool population is Negro. The racial difference in incidence is believed to be due to environmental factors probably resulting chiefly from economic disadvantage.

For the past few years information has been collected on home ownership in neighborhoods where child lead poisoning cases occurred. Almost 90 percent of the houses were tenant-occupied. In the early years of the study some of the cases arose in well-kept property, but with the continued community education by press and radio, cases in this category have become relatively rare. The problem in Baltimore at present involves chiefly slum or blighted-area properties. The cases are concentrated in two areas which are of known slum status and where the houses are old and have had many coats of paint, usually lead paint, applied throughout several decades. A typical home where a case of lead poisoning occurred is shown in figure 2.

Methods of Prevention

Education and Publicity

In an effort to prevent lead poisoning, repeated public warnings about this child health hazard have been given by the Baltimore City Health Department in the press, by radio, and on television. The *Baltimore Health News*—mailed each month to over 10,000 persons, including 1,800 local physicians and 6,000 school teachers—devoted a number of issues (2, 46, 47) to the subject. The bureau of child hygiene issued a leaflet (45) entitled "Lead Poisoning in Children, a Disease You Can Prevent." The leaflet directs attention to 220 cases and 78 deaths from lead poisoning in Baltimore during the past 18 years, makes suggestions to parents for preventing children from contracting the disease, lists the warning sig-

nals to be watched for, and stresses the importance of early diagnosis and treatment.

It is not unusual now for a mother to take a child to a physician and to volunteer information on pica and suggest that the child may be suffering from lead poisoning.

The Public Health Nurse

One of the most promising advances in the prevention of child plumbism was the assignment several years ago of a public health nurse supervisor to investigate lead poisoning cases. With the knowledge gained by intimate association with the problem, the supervisor was able to interest other public health nurses. They not only make home visits and disseminate information in the most-affected areas of the city, but may take part in well-baby clinics, where mothers are told of the dangers connected with pica.

Lead Paint Removal

For the past 4 years, landlords of properties where lead poisoning has occurred have been notified, in accordance with the Baltimore ordinance on the hygiene of housing (44), to remove lead paint from the surfaces where there is flaking or where a child has chewed. Of 96 such notices during this period only 2 were not complied with in the time allotted. Both owners were summoned to the Magistrate's Court, where they were found guilty and fined; only then did they fully comply with the health department's orders. Many sanitarians on the health department staff who inspect property, primarily on the basis of other types of complaints or because of rodent and housing surveys, also require correction of a flaking paint condition in the notice sent to the property owner. The sanitarians are instrumental in the distribution to slum dwellers of the leaflet on the lead poisoning prevention (45).

Legislation

Because of the danger to small children, manufacturers of cribs and toys have for many years (9, 17, 48) used paints free of lead pigment.

For various reasons legislation against the use of lead paint has existed in widely separated jurisdictions for a number of decades. Germany has had a national law on the matter

Figure 2. House doorway in home of patient with lead poisoning.

since about 1900. Regulations prohibiting the use of lead-containing paints on toys, children's furniture, and for interior work have been enforced in France since 1917 (17). As early as 1922, the nations adhering to the International Labor Office in Geneva proposed a convention prohibiting the use of white-lead paint in interior painting of buildings as a health measure affecting painters (49). Since 1932, factory legislation in Ontario has required all lead-containing paints supplied to plants manufacturing children's toys and furniture to be so labeled (17, 48). No cases of lead poisoning related to chewing on new furniture or painted toys have been reported in recent times. When such objects are involved, the source of lead has been repainted furniture—parents frequently use lead-base paints for repainting jobs. Nevertheless, the Maryland State Legislature in 1949 enacted chapter 517 of the Acts of 1949, which

made it compulsory to affix a label to any toy or to any children's furniture decorated with paint or other material containing lead or any other poisonous substance, stating clearly the poisonous nature of the paint or decoration. Unenforceable, the law was repealed a year later.

On June 27, 1951, regulation No. 17 was adopted by the commissioner of health of Baltimore under the ordinance on the hygiene of housing. The text follows:

Interior Painting. No paint shall be used for interior painting of any dwelling or dwelling unit or any part thereof unless the paint is free from any lead pigment.

The wording was studied carefully so as not to prohibit the use of paints containing either lead driers, usually present in amounts corresponding to less than 1 percent of lead in the finished paint, or pigments contaminated with

traces of lead. The use of the term "lead-free paint" was purposely avoided, since it is doubtful if the usual commercial product could be made without having a detectable amount of lead present. This regulation has had pronounced salutary effect as shown by an increasing interest on the part of home owners, health agencies, and local paint manufacturers, some of whom have recently advertised paints free from lead pigment.

Lead Content of Paint

The health department's suggestions to parents interested in the purchase of "lead-free" paint emphasizes a selection based upon the labeled composition of the product. Although there is no Maryland law on the subject, many of the paints sold locally contain a statement of composition on the label. Such labels provide information on the presence of lead-bearing compounds and are adequate except in those instances where the terms "chrome yellow," "chrome green," or "chrome orange" camouflage the fact that these pigments contain substantial amounts of lead chromate. For this reason, when inquiry is made, it has been recommended that no yellow, green, or orange colors be used in refinishing articles of furniture intended for use by children unless the pigment composition as declared on the label clearly excludes the presence of lead.

Summary

Lead poisoning in children caused by ingesting lead from surfaces coated with lead-containing paint is apparently widespread throughout many parts of the Nation.

The disease has a high rate of incidence in the city of Baltimore, where it occurs in children of teething age living in old, run-down rented properties where lead paint had been used indoors for many years.

Public health education, coupled with a "lead consciousness" on the part of physicians and the pediatric clinics of local hospitals, and with a blood-lead laboratory service offered by the city health department has resulted in a marked increase in case recognition.

It is hoped that the application of principles

involving education and the enforcement of measures regulating the use of lead-containing paints will result in a material reduction and the eventual eradication of child lead poisoning in Baltimore City.

ACKNOWLEDGMENTS

The authors are indebted to Matthew L. Taback, director of the bureau of biostatistics, and to Margaret Galbreath, supervisor assigned by the bureau of public health nursing to the bureau of industrial hygiene, for assistance in the preparation of this article.

The Mental Hygiene of Aging

By PAUL V. LEMKAU, M.D.

Mental hygiene, the extending of satisfactions of living and the decreasing of the incidence and prevalence of mental disease, is as feasible for older as for younger groups. Two basic concepts underlie this belief: First, there is apparently no complete and direct relationship between the anatomical changes in the brain and the behavior of the personality possessing it; second, the capacity to function is lost when not exercised.

The first concept is illustrated by the fact that some persons with severe senile degenerative brain changes are able to exist outside of psychiatric hospitals, maintaining their behavior within the bounds tolerable to society. Others with no more severe changes, show behavior which cannot be tolerated and these must be hospitalized. The relationship between brain changes and behavior is influenced by the specific location of degenerative processes in the brain and by the extent of generalized loss of brain cells. If the loss is extreme, behavior must degenerate. If it is not extreme, the extent of change does not completely account for behavior alterations.

The most startling examples of the second concept, that functions atrophy when not in use, come from the period of early infancy and are described by Gesell (1), Bowlby (2), and others. An isolated child who hears no speech and is not encouraged to speak will not speak, and eventually becomes incapable of learning to speak. In the same way, the child deprived of

the opportunity of forming social relationships will eventually lose the capacity to make such relationships.

In the animal world, status in the society has been shown to be relatively fixed by the "experiences" of the animal in question (3). The mouse, at the lower end of the scale of aggression in his life situation, can be raised only by having a number of battles carefully arranged for him in which he is easily the conqueror. The mouse or rat who is always defeated in battles with his fellows is less aggressive and physically weaker. He becomes smaller than others in his group, probably because he gets only left-overs to eat, and not enough of them. His capacity for aggressive behavior atrophies in the face of continual frustration.

Wide Range of Interests

All this leads to the conclusion that it is well for human beings to maintain as wide a range of interests as possible throughout life. It is well, too, to entertain and react to a broad range of stimuli in order to avoid atrophy of capacity for the reception of stimuli. Brain cells, though present, may not function to maximum capacity because they are deprived of nutrients, either lacking in the diet or not delivered to the cells because of poor circulation. Through general medical care and proper nutrition, however, brain damage in the catabolic period can be reduced to the minimum.

We can also reduce functional atrophy of the personality to a minimum. Atrophy of this sort comes rapidly in infancy and early childhood when range of function is expanding explosively. There is probably a long period of dormancy before the death of functional ca-

Dr. Lemkau is adjunct professor of public health administration, division of mental hygiene, School of Hygiene and Public Health of the Johns Hopkins University.

capacity in the mature personality. Lillian Martin and others have demonstrated that capacities which seemed lost in older individuals were not lost but only covered by the dust of disuse (4). Like Navy ships laid up between emergencies, coverings can be pulled off and functions made ready for action when the stress of the times is great enough.

These two basic concepts of mental hygiene for the aging—one relating to organic and one to functional changes—are not, of course, independent. One of the great problems in obtaining proper nutrition for elderly people, for instance, is getting the individual interested in his diet. He must be stimulated to eat enough of the nutrients which keep his brain working at maximum efficiency. Only then will he have the ability to react to stimuli presented.

It is always necessary to look at the factors in an older person's life which affect his ability to receive stimuli. Moreover, it is always a problem to assess how much of the loss of ability is due to organic, how much to functional, how much to mixed factors. In many instances, diagnosis is possible only during therapy. In some cases it is never possible to separate factors into those based on cell damage and those caused by inability to function because of habitual disuse.

What Is Mental Hygiene for the Aging?

To avoid loss of ability to receive stimuli, the individual must maintain his physical health at its maximum. Equally important, he must try to delay narrowing the range of his interests and activities through the constructive and creative use of leisure time.

Bringing physical status to its maximum level and maintaining it there is no simple task. It may be necessary to use psychological procedures to achieve this maximum, but these procedures are then a means to an end, and not basic mental hygiene. The field of hearing defects provides frequent examples of the neglect of the physical side of rehabilitative procedures. Surprisingly enough, many forget that the first principle of mental hygiene for the hard of hearing is the maximal restoration of hearing through treatment or through the use of artificial aids. Until the maximum

possible physical ability to react to stimuli is reached, psychological procedures must take second place.

The capacities of a person to receive stimuli from the world about him decrease as he becomes older. Sight, hearing, muscle sense, tactile sensibility, and pain sensitivity all diminish progressively with increasing age. This may make it easier for the older person to allow functions to slip into disuse. The stimuli received from a symphony orchestra, for example, may be so slight that it is easy to skip concerts. Or it may be so difficult to hear a union leader as he conducts a meeting that it is easier to stop going to meetings. The emotional stimulation of discussion is lost and social contacts restricted. The life of the older person settles into a narrower path.

Change of Interests

Thus, aging is accompanied by a change of interests. The general pattern of this change is away from variability or activity and in the direction of rigidity and decreasing physical movement. Small groups are preferred to large, talking is more congenial than more active entertainment. There is a tendency, shown by psychological testing, for reactions to take longer to reach completion. All these things are probably of little consequence when they affect a person with a large store of experiences available to furnish what Adolf Meyer called "resting points of satisfaction" (5). But for those whose total range of experience has been small, whose life energies have been poured into few channels, they may mean almost complete extinction of interests and activity.

This is particularly true for the man who is suddenly forced to retire because of ill health or company rules. A professor may find retirement a period for accomplishing things he has often wished he had time to do. On the other hand, the executive interested only in winning as much as possible at the game of business and in losing as little as possible at golf may find his life empty when he retires and can no longer take strenuous exercise. The moving picture, "The Steps of Age" (6), dramatizes the vacuum resulting from the retire-

ment of a skilled workman. Rare is the man who can look forward to the respectable position of "elder statesman." Most of us must find satisfactions of our own making; we must be secure enough in our own enjoyments so that we can get along on a somewhat reduced status in the community.

"Retirement" for the woman who is the mother of a family is generally not so sudden and shocking as for the man. It comes earlier for her than for him; it is never so complete. The departure of children from the home is rarely as final or sudden as the separation of the man from his work when he retires. Household duties and responsibilities diminish gradually and rarely completely disappear. Work hours in the home are more flexible than in industry, and time can be taken out during the day for social, religious, and other types of group activity. Grandchildren extend the period of adaptability and flexibility of personality for many aging women, while their husbands are denied this salutary influence. One wonders whether this may have something to do with the greater longevity of the female in our culture.

A basic task of the mental hygiene of aging, then, is to make life after retirement an opportunity for the maintenance of a broad range of interests. The idea of prophylaxis against damaging social and emotional crises is not a new one in preventive medicine. It is fundamentally no different from universal vaccination to prepare a population to withstand a possible typhoid epidemic. Medicine needs to be equipped with health education techniques to deal with this sort of problem as well as with more familiar ones. The use of leisure time so that it satisfies us when our only time is leisure is one of these concepts.

Our problem now is how to help older people "with nothing to do that means anything." We must try to see that their lives are made more satisfying, that emotional deprivation does not lead them to behavior disorders intolerable to society. This is a job that must be done, unfortunately, in a short time. It should have been done throughout the lives of the personalities involved. The fertilized ovum is the beginning point in general mental hygiene thinking; the aged personality is a slate on which many, many

words have been written, many formative experiences inscribed. The task is all the more difficult because of the progressive loss of ability to receive outside stimuli.

Socioeconomic Problems

Many problems of great concern to the mental hygienist in helping older people are socioeconomic and can rarely be controlled. The older person must pay for housing and food. Even when he can afford these essentials of living, he rarely has much cash left with which to cultivate new interests or even to continue old ones. In cultures in which the parents remain the heads of families as long as they live, their status is likely to grow with age. Consequently, their livelihood is the natural result of their ownership of the means of support for all the family. In our culture, however, children are urged to stand on their own feet, to become independent in their own right, and to be emancipated from the paternal hand. Furthermore, our modern industrial economy does not give the child the opportunity to work with his parents and establish a common economic goal with them.

So the concern of children for their parents' support is likely to be lost, and parents must rely on their own resources when they are no longer able to work. Very few are able to save enough during working years to provide independence in old age. In an inflated economy, present social security allowances, when substituted for wages, can result only in radical lowering of standards of living for many people. This lower standard may mean less satisfactory housing and insufficient amounts and variety of food.

More and more frequently, elderly people in our culture have difficulty living in the homes of their children. Once the child has broken away from the home, he seems no longer able to offer sufficient status to the parent as a member of his household to make life run smoothly. Old struggles are reactivated, the gap between the generations becomes too large to be bridged by understanding and acceptance. Permanent, comfortable, cooperative existence under the

same roof cannot be expected. Many elderly persons recognize this and resolve to live alone. Some succeed, but others are forced by inadequate finances or by concepts of parental and filial duty to live uncomfortably and under stress with their children. The high cost of modern housing, which means small houses and apartments, has markedly aggravated this situation.

These problems have been attacked in two different ways. Subsidized housing exclusively for elderly people has been built or adapted to their needs. The result has allegedly been good, not only because of the housing itself, but also because this housing usually is combined with programs for recreation and other socialization. In some places, daytime programs have been set up to provide recreational and social opportunities without any attempt at changes in housing.

The elderly person is likely to be lonely, particularly if he is widowed or not in his own house, in control of his own life. The aging process has made movement difficult and slow. It is hard to travel to see old friends, particularly if they have been scattered by changes which destroy old, familiar neighborhoods. When friends have died, too often the gap they leave in the lives of their contemporaries can never be filled because no one else is available to fill the niche. This means further emptiness and loneliness for many old people, a reduction of stimuli and, thus eventually, lessened function.

Group Activity

The gathering together of older people in communities so that they can keep the roster of friendship full and stimulating has become a recognized social service and mental hygiene measure in recent years. It has been done as a special program in connection with city community centers. Frequently, and apparently without too much difficulty, it has been combined with other types of emotional and intellectual stimulation. Older people gather together for dances, parties, games, conversation, sometimes even courtship. They show willingness to join classes and learn new skills

that will give them creative outlets for hours which might otherwise be empty. The young man may be driven by ambition to educate himself, but the elderly person grasps the opportunity best under the heightened stimulation of group activity.

This type of mental hygiene activity is of relatively recent origin and, in many places, is not yet well developed. It needs to be greatly expanded. Group activities for elderly persons can be performed under the auspices of mental hygiene or church societies. The leader in charge should remember that older, more than younger folks, need a feeling of status, of control over their own destiny. He should act as a catalyst, or helper, leaving direction of the group to its own members, not to planners "doing something" for the elderly. And when it is impossible to bring groups of older people together, it may be feasible to bring outsiders to them in their homes. Some philanthropic societies have set up continuing programs for finding isolated older people and bringing stimuli to them through regular visits. These stimuli include various types of handiwork which, when completed, satisfy the need of the older person to produce something which will justify his existence.

Such programs present many problems. There is the social background of the people in the activity group. Judy O'Grady and the Colonel's Lady may be sisters under the skin, but they won't want to do the same things in a recreation group, and the direction of their creativity will be different. Some attempt at initial selection should be made, but there should also be provision made for the older person to select the type of group with which he can feel most comfortable. And there is the problem of transportation unless the programs are combined with special housing. For these reasons, neighborhood groups are probably desirable.

Goals

The opportunity to work for pay, if a man is willing and capable of doing so, would greatly reduce the mental hygiene problems of the aged and is a goal worth working toward. But even if this goal is achieved for some, there will be

many older people left to profit from learning to use and enjoy leisure time through the activities outlined above. Such activities bring happiness and relief to the elderly. They are also a means of preventing, or greatly delaying, the appearance of symptoms of mental disease and thus of sparing society the high cost of hospitalization. However, there are no conclusive data available to evaluate this point. Admissions to psychiatric hospitals are a good index provided that the availability of beds is equal in the areas compared (which is not usually the case). The fact that 31.5 percent of admissions, for instance, to New York State psychiatric hospitals in 1947 were recruited from the group aged 65 and over (7) indicates the tremendous practical importance of finding and evaluating ways of postponing or making unnecessary hospitalization for mental illness. Proof that programs such as those discussed here actually accomplish this would be a great stimulus to their expansion. These data should be less difficult to obtain on older than on younger groups since the number of variables to be controlled is reduced among older people.

There are many compelling reasons for carrying out mental hygiene programs with the aged. Certainly one of these is the probable prevention of the social and financial load of

psychoses of old age. Another is the fact that a goal for youth is a satisfying old age. If this goal could be assured, many of the pressures and insecurities of younger people would be relieved. The giving of health, the helping to lead an aging person to a more abundant life—one with satisfaction instead of loneliness, with joy in creation instead of frustration, with pleasure in social contacts rather than irritation in meeting people—these are the most important aims of the mental hygiene of aging.

You Can Be Safe From X-Rays

16 mm., sound, black and white, 10 minutes, 1952.

Audience: Personnel concerned with operating X-ray equipment.

Available:

Loan—Medical Directors, (PHS) Federal Security Agency Regional Offices. Also from Communicable Disease Center, PHS, P. O. Box 185, Chamblee, Ga.

Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

This filmograph was prepared by the Division of Chronic Disease and Tuberculosis of the Public Health Service, as a training aid for X-ray technicians and other personnel. It stresses the hazards of secondary radiation in X-ray installations and outlines protective measures against overexposure to radiation. In cartoon style, it depicts an X-ray technician who takes excellent care of his equipment but does not use the same care in protecting himself from the harmful effects of too much X-ray exposure. The effects of excess radiation are discussed, the hazards outlined, and protective measures de-

scribed in detail. The point is emphasized that X-ray can be safe when those who handle it know the facts and follow simple safety rules.

Sanitary Landfills in Northern States

— A Report on the Mandan, North Dakota, Project —

By RALPH J. VAN DERWERKER, B.S.

Of 135 North Dakota municipalities surveyed in 1947-48, only three used incinerators for refuse disposal, and three others relied on the open-face dump type of sanitary landfill. The open dump was the only answer to the problem in 129 communities.

Seeking a sanitary solution to the refuse disposal problem, the North Dakota State Department of Health invited the Public Health Service to participate in a study of the use of landfill techniques for small cities and towns in cold climates. The city of Mandan, which has a population of 7,298 (1950 census) and where winter temperatures of -30° to -35° F. are not uncommon, was selected for an experimental landfill project. In the spring of 1949 the project got under way.

By agreement, the city paid for an equipment operator and other costs, in addition to providing the site. The State was responsible for office and travel expenses. The Public Health Service obtained the necessary heavy equip-

ment and assigned a sanitary engineer to take charge of the project.

When the official participation of the Public Health Service ended with completion of the first year of operation, sufficient data had been accumulated to show that the sanitary landfill satisfactorily and economically could solve the problem of refuse disposal for northern communities. However, at the beginning of the second year, another Public Health Service sanitary engineer was assigned to the project to continue gathering data for another year.

Site Selection

The choice of landfill sites narrowed down to two: One included some 20 acres of land located a little over 1 mile from the main street; the other was an open-face dump operated by the city on low, submarginal land which filling would make usable. The latter, however, was close to the center of town, and because of the experimental nature of the project the city commissioners favored the out-of-town site. The Public Health Service engineer approved of the out-of-town site because it was particularly well-suited for the trench-type of landfill and thus would have more demonstration value for other communities.

The selected site was elevated considerably above the surrounding terrain, well exposed to the high winds prevailing in the area. It had a 2.5 percent slope at the southern end, rising gradually to 6 percent at the north. There was a shallow ravine in the east-central portion,

Mr. Van Derwerker is the chief of the municipal and rural branch of the division of sanitation, Bureau of State Services, Public Health Service. This paper, a review of the operation of the Mandan project, is based on progress reports made by the project engineers, Leo Weaver and Donald M. Keagy, division of sanitation, Public Health Service. A detailed technical report of the experiment is being prepared for publication.

and a deep coulee on the northeastern end. Excellent drainage existed. Soil analysis showed 64.2 percent sand, 13.5 percent silt, and 22.3 percent clay.

It was decided to construct the fill in the form of a wide U so that refuse could always be dumped with, instead of into, the wind. A topographical map facilitated accurate planning with respect to grades, size of fill site, and other work. The fill when completed would be a uniformly sloping field with excellent drainage.

Operation

The first trench was excavated in June 1949. The original trench width of $1\frac{1}{2}$ times the width of the tractor was increased later to $2\frac{1}{2}$ times (or about 17 feet) to permit more maneuverability for backing the collection truck into the trench in order to protect the refuse from high winds. Experience shows that too wide a trench, however, reduces efficient operation, since too much cover material is required each evening.

The usually recommended trench depth for a sanitary landfill is about 3 feet for a one-level fill. The average depth at Mandan, however, was 6 feet in order to provide extra protection from the high winds and additional dirt for a two-level fill. The extra depth encouraged careful dumping by individuals, after hours, since they seem to prefer to throw refuse into an excavation rather than on the surface.

The two-level operation proceeded as follows: First, the refuse was placed in the trench and compacted to 5 or 6 feet (fig. 1). Then,

Figure 1. Construction of first level of fill.

Figure 2. Construction of second level of fill.

it was covered with 9 to 12 inches of dirt. When enough area on the first level had been built up to permit free operation of the tractor and dumping vehicles, the second level was started (fig. 2). This type of operation made it possible to use the lower level when strong winds were blowing, and the upper level during periods of calm. Cover material for the upper layer was obtained by excavating the next trench to be used at the lower level.

Experimentation with various depths of cover material indicated that 2 feet of cover under average conditions will result in not less than 1 foot at all points, which is sufficient for sanitary purposes. Approximately 5,518 cubic yards of earth were dug and used for cover during the first year of operation. This gives a volume rate of 4.7 acre feet per 10,000 population, as against a generally accepted rate of 6 acre feet per 10,000. The reasons for the lower rate at Mandan were, probably, that the quantity of domestic ashes was small, due to the extensive use of natural gas, and that Mandan does not produce the large amounts of solid, industrial wastes common to many other towns.

It was essential to guard against mixing too much dirt with the refuse. Otherwise, the available cover material is too rapidly depleted, and the trench becomes deeper than is desirable.

Controls Necessary

Operations were impaired at first by the absence of regulations establishing daily hours for dumping. The fill was left each evening in neat and orderly condition, and the records

show that no fires ever started in completed cells. However, material dumped indiscriminately during nights and week ends caused fires and created public health and nuisance hazards, which made it necessary to establish and enforce strict dumping hours.

The city collected refuse from the residential areas on a fee basis, but business establishments either hauled their own or contracted with private haulers. Some difficulty was encountered in trying to get the latter to dump at specified points. This was overcome gradually through the encouragement of community support by means of an active public relations program, principally by means of articles in the local newspapers. The operator-foreman was very helpful, also, in patiently explaining the operation to all visitors.

Paper and Fire

Windblown paper constituted a serious nuisance, even though the problem had been anticipated. The erection of a windrow, the two-level design, the depth of trenches, and the U-shape of the fill, all had been planned to counteract the effect of high winds. In addition, a 4-foot chicken-wire fence was erected, but it was not particularly effective in overcoming the problem. Subsequently, the problem was solved by the use of snow fences.

The paper collected from the residential areas was well mixed with garbage, and was not much affected by the wind, but refuse from the business district was mostly paper and created a greater problem.

Fires seldom, if ever, occur in properly compacted and covered refuse, but they may occur in material deposited during the day or when the operator is off duty. Hot ashes may smoulder unnoticed, and suddenly burst into flame; refuse compacted in a truck may blaze suddenly when dumped and exposed to air. Daytime fires can be extinguished quickly by covering and compacting. Trucks carrying smouldering material were also unloaded at the unused end of the trench, or in another trench.

Vermin

Daily compaction and covering of the refuse seemed to eliminate any fly-breeding or rat-

breeding problem. Flies, however, followed each truck during hot weather and were drawn to bits of garbage adhering to the tractor, necessitating the spraying of the tractor with DDT in order to protect the operator. On larger projects, it may be necessary to make scheduled use of insecticides on the truck bodies and over the site.

Preparation for Winter

Original plans called for the preparation of a trench 300 feet long, 6 feet deep, and 22 feet wide, to be prepared and placed in reserve for winter operations. However, because of the limited data available on volume of refuse, it was later decided to dig a second reserve trench, which measured 100 feet in length, 25 feet in width, and 6 feet in depth.

The second reserve trench actually had to be put in use early in March 1950. The continuance of winter operations was insured by this foresightedness. Refuse delivered to the fill in February averaged 69 yards per working day, or a total of 1,656 yards. Experience showed that a reduction of 65 to 75 percent could be obtained through compaction.

To provide cover material for the time when it would be too cold to dig, about 700 cubic yards of dirt from trenches dug in the fall was stockpiled as close to the working area as possible. The practical distance for a stockpile seems to be up to 100 feet from a trench. Probably a limit of 50 feet should be set when a crawler tractor is used.

The stockpiles were built with their axes parallel to the prevailing northwest winds to keep them comparatively free of snow, and their sides were sloped steeply to shed rain. With a moisture content at excavation time of 9.2 percent, and of 4.9 percent when sampled from the stockpile in January, lumping never became a serious problem when moving earth from the pile for cover.

Winter Operation

Over 72 inches of snow fell up to April 1—more than ever before recorded; and more fell during April. On recommendation of the State highway department, however, snow

Figure 3. Old dump area prior to landfill operations.

Figure 4. Dump site after landfill operations.

fences had been built at the landfill site. Drifting, therefore, caused no difficulties, and snow did not accumulate in large quantities in the trenches.

The temperature in January 1950 averaged -10.2°F .—a new record for the month—with a minimum recorded temperature of -44°F . The entire winter was severe, as indicated by the fact that the Missouri River ice break-up did not occur until April 15, later than ever before. But equipment problems were surprisingly few. The daily starting of the diesel-driven tractor was made possible through the building of a garage at the site, in which an oil stove, burning continuously, kept the temperature at a constant 20° to 30°F . A well-constructed, heated cab in the tractor is essential. Also, the tractor was equipped with grousers for use on ice or hard-packed snow.

Other Experiences

Experience at places other than Mandan indicate that winter landfill operations may be facilitated by one of the following procedures:

1. Plow or scarify the area to be excavated before the frost arrives and place insulating material (leaves, hay, etc.) to a depth of at least 3 feet, replacing the insulating material over the working area as the trench is excavated.

2. Excavate the required number of trenches in advance, and stockpile the cover material. Work the stockpile, if wet, to insure drying, and protect it with leaves, placed in the form of cells, with each cell being opened as cover material is needed. Leaves should also be mixed into the pile.

When spring floods cut off the approach road to the trench landfill site, in March 1950, operations were moved to the vicinity of the former open-face dump, where an area type of landfill was started (figs. 3 and 4). The speed and ease with which the move was made indicate the versatility of the landfill method of disposal.

In the new area, water from the spring run-off stood 3 feet deep, making it impossible to obtain cover material by trenching. Cover material was obtained from various places—from the upper layers of the old dump, from a nearby hill, etc.

The depth of the new fill was from 12 to 15 feet. Therefore, refuse was deposited in two layers, for the same reasons which dictated this type of operation at the original site.

The rat population at this dump, of course, had been eliminated when dumping was discontinued. Otherwise, the rats would have migrated to new food sources, with consequences which could have been tragic to the residents of the community. Under supervision of the United States Fish and Wildlife Service, poisoning operations were carried out by employees of the city street department.

Cell Temperatures

High temperatures in a closed cell result from anaerobic bacterial activity and digestion of organic material. The degree of heat and its duration are excellent measures of the bacterial action. The following temperature data are presented from the experiment conducted at Mandan.

Temperature graphs were maintained on three test cells, identified as C_1 , C_2 , and C_3 , from

January 1950 through June 1951. The first two cells were located on the original landfill site, and the last on the new site at the former city dump. These graphs were combined with a graph of the daily atmospheric temperatures to show the relationship between air temperature and temperatures in the cells (fig. 5).

Figure 5. Comparison of monthly averages of cell and atmospheric temperatures, Mandan landfill project.

Refuse was deposited in cell C_1 in November 1949 and the cell was closed, but temperature-recording equipment was not available until January 1950. From then through May 1950, the graph shows that a stable temperature was held, apparently independent of atmospheric conditions, including the winter period.

Cell C_2 was completed in January 1950. The conclusion reached from the temperature graph for this cell is that refuse placed, compacted, and covered in freezing weather generates little or no heat from decomposition until atmospheric temperature rises high enough to permit bacterial activity.

Cell C_3 was started and completed in warm

weather. The internal temperature of the cell rose to a peak of 93° and fell to 83° F. within a single 2-week period. The rise to only 93° F. indicates a high content of inorganic material in the refuse.

The temperature data also show that the temperature peaks in the three cells were considerably lower than the 140° to 180° F. frequently mentioned in literature on similar studies. Probably the reason for the slow decomposition of the refuse was the high paper and cardboard content which did not provide optimum environment for bacteria. It may be necessary, in similar operations, to provide a catalyst in order to promote complete bacterial reaction within a reasonable time.

The equipment used for temperature-recording was not expensive, and should be within the reach of any community. It was comprised, basically, of a maximum-registering thermometer, which is familiar to all milk sanitarians, and a prepared 6-foot length of pipe. The thermometer mentioned cannot be used when atmospheric temperature is greater than cell temperature. For a complete year-long record, a dial-type thermometer is needed.

Refuse Analysis

The laboratories at the Environmental Health Center, Public Health Service, in Cincinnati, Ohio, performed monthly chemical analyses of raw-refuse samples from Mandan through the year 1950, with the exception of November. They also made analyses in July 1950 and July 1951 of samples of refuse which had been buried in July 1949.

Probably the most significant indication of bacterial action already accomplished and remaining to be accomplished was the BOD (biological oxygen demand) results. The BOD dropped from an average of 77,050 ppm for the fresh garbage and refuse, to 30,000 ppm for that buried for 1 year, to 23,500 ppm for that buried for 2 years. These figures appear to follow an asymptotic curve, as would be expected. However, it appears that even after 2 years of burial, a considerable amount of bacteriological decomposition remains to be accomplished under the climatic conditions of the North.

Settlement and Soil Analysis

Data compiled concerning the percentage and time of settlement showed that (1) the minimum percentage of settlement over a 24-month period was zero, (2) the maximum over a 17-month period was 18 percent, (3) the lowest percentage of settlement occurred in the first cells, which were constructed during the summer, and (4) the highest percentage occurred in the cells constructed during the winter.

The rate of settlement, however, is affected by many variable factors: the skill of the operator in placing, compacting, and covering the refuse; the percentage of garbage in the refuse; the percentage of dirt mixed with the refuse; the amount of travel over completed cells by tractors and trucks; the depth of individual cells; and weather conditions at the time refuse is deposited. The last factor includes the probability that the operator will do a less thorough job of compacting at 20° below zero than at 60° above, and the fact that frozen refuse is less compactable. Therefore, it is difficult to predict accurately the percentage of settlement that a sanitary landfill in a cold climate will show.

Adequate standards which will enable an engineer to submit a soil sample from a proposed landfill to a soil laboratory and receive sound information on all the problems he may encounter remain to be developed.

In the meantime, H. W. R. Larson, of the Bureau of Reclamation Soils Laboratory, Bismarck, N. Dak., has suggested that all soils be submitted for mechanical analysis. In the case of heavy soils, Dr. Larson recommends determination of the sulfate ion as a test for gypsum content, and determination of the lime content as a test of porosity. These would indicate how easily the soil could be handled. Also, for heavy soils, Dr. Larson states that determination of exchangeable sodium will tell whether or not the soil will work in lumps.

Weight and Volume

Weighing of the Mandan refuse was begun in February 1950 and continued through May. Of course, for reasonably accurate weight and

volume data, a full year's figures are desirable. However, two interesting facts were uncovered from the 4-month experience: (1) an average weight of 3 pounds of refuse per capita per day; and (2) an almost equal division between refuse from the business district and that from the residential areas.

For purposes of comparison of one community's experience with that of another, weight records are much more reliable than volume estimates. The Mandan experience indicates the unreliability of cubic yardage figures. Loads on the 12-yard packer truck varied from 60 to 80 percent of capacity, depending on the truck's mechanical condition. Therefore, an assumption that 50 loads totaled 600 yards could be up to 40 percent erroneous. Also, yardage from a nonpacker truck obviously cannot be considered the same as that from a packer truck.

Costs

The average monthly cost of operating the sanitary landfill at Mandan, based on a 10-month study, was \$432.98. This figure includes the pay of the equipment operator (\$235.91 for an 8-hour day and a 6-day week); \$27.73 for fuel, grease, repairs, and other operating costs; \$22.34 for general expenses, such as fencing, land, etc.; and \$147.00 for tractor amortization (\$8,000 at 4 percent over a 5-year period).

The average amount of refuse deposited monthly (February through May 1950) was 327.55 tons. Applying this 4-month weight average to the 10-month cost average shows a disposal cost of \$1.32 per ton. This means an increase in the monthly disposal cost of \$282.98, or of 86 cents per ton, since Mandan had previously paid a dump attendant \$150 a month.

The 10-month period included 255 working days, during which the tractor and operator worked a total of 536 hours, or 2.1 hours per working day. Assuming that they were used on other municipal projects for only one-half of the possible working time, a reasonable cost estimate for the operation of the landfill could be worked out as follows:

Wages (4-hour day, 6-day week)-----	\$117.50
Operating costs-----	30.00
General expenses-----	25.00
Amortization-----	73.00

On the basis of 327.55 tons of refuse per month, this computation brings the cost per ton to 75 cents.

Repair costs over a 5-year period will, as a rule, be larger than those shown in the Mandan experience, but they may be offset somewhat by salvaging used equipment, by careful operation and maintenance of equipment, and by judicious use of municipal repair facilities and labor.

Note that these estimates include amortization of equipment, which few communities consider in their cost tables. Eliminating the amortization figure reduces the cost per ton to 53 cents, which is comparable to the unit cost commonly reported for a sanitary landfill.

In final analysis, actual landfill costs will depend on what a community charges to operation, and on planning and efficiency.

Conclusions

The primary purpose of the Mandan experimental sanitary landfill project was to determine if this method of refuse disposal would be practical in the colder portions of the United States. The winter operation in Mandan has answered this question affirmatively.

With proper planning and efficient operation, a community of 5,000 population should be able to manage a sanitary landfill. On a project of this size, the tractor is required for only 2 or 3 hours a day, and is available the rest of the day for gravel loading, snow removal, street excavation, or other municipal requirements. Such an arrangement, of course, would make it essential to regulate dumping hours at the fill

strictly, to prevent the scattering of refuse during evenings and week ends.

Communities smaller than 5,000 population might modify the landfill method with a form of sanitary trenching. In this, of course, it would be necessary to clean up the site before digging the trench. Usually, the accumulation on small dumps can be moved only by heavy equipment; thus, the trench may have to be dug by county or rented equipment. In this form of operation, the refuse should be compacted and covered at least twice weekly in warm weather, and as often as practicable in the winter.

A small road scraper or bulldozer can be used if heavy equipment cannot be obtained. Large items, such as tree limbs, car fenders, barrels, etc., would have to be removed by hand.

The steps in the operation of a sanitary trenching area by a small community can be itemized as follows:

1. Clean up the old dump and exterminate rats.
2. Build an all-weather road to the site.
3. Dig a trench, storing dirt at the ends or on the sides.
4. Designate a specific area for large objects.
5. Work over the refuse in the trench, and cover the top and face with at least 2 feet of dirt.
6. Each spring, incorporate the large objects into the fill, burn the accumulated brush, and dig a new trench.

Sanitary trenching is not as good a method of disposal as a sanitary landfill, but it is a vast improvement over the usual open dump.

Coming in Public Health Reports

Tests of 2,4-Diaminopyrimidines On Toxoplasmosis

By DON E. EYLES, Sc.D. and NELL COLEMAN, A.B.

Tests of several compounds of the 2,4-diaminopyrimidine group have shown two members of the group, particularly 2,4-diamino-5-(4'-chlorophenyl)-6-ethyl pyrimidine (DCEP), to be active against toxoplasmosis.

DCEP is an effective antimalarial drug, as shown by Falco and associates (1), with a proguanil equivalent of 40 against *Plasmodium gallinaceum* and 200 against *Plasmodium berghei*.

To test their antitoxoplasmic activity, DCEP and related pyrimidines were screened by our laboratory for their effect against *Toxoplasma gondii* in the mouse. We are reporting the results of these screening tests and more extensive tests with DCEP.

Methods

Young mice (weight about 20 gm.) of the NIH general purpose strain and a strain of *T. gondii* isolated by this laboratory from the Norway rat were used in the tests. With an intraperitoneal inoculum of 20,000 organisms, prepared by diluting peritoneal exudate with physiological saline, mice invariably died, usually in 7 ± 1 days. Six mice so infected were used in the screening of each new drug. Un-

treated controls and clean controls were kept for each group of tests.

Drugs were administered in pulverized diet starting just after inoculation and continuing for 14 days. Dosages are stated as milligrams percent in diet and were at the maximum tolerated dose (MTD) if it was known. Conversion to milligrams per kilogram was made by using an average daily food intake figure of 4 gm. Drug activity was measured by the degree of prolongation of life of treated mice over the controls. Significance was measured by comparing the mean duration of life of the untreated and treated groups by means of the T-test (6).

The more extensive tests with DCEP required the determination of the dose-effect relationship against similarly induced infections. Nine or more mice per dosage level were used. The Litchfield and Wilcoxon (4) method of calculating the median effective dose (MED) was utilized. Since cure was infrequent, the MED was defined as the dose which permitted half the mice to survive 10 days or longer. Ten days was the period used because the test showed greater sensitivity at that time than at 14 days, thus facilitating comparison with less active drugs and with drugs of limited supply, which necessitated a shorter treatment regimen.

Results

The results of the screening tests are given in table 1; results of one test with sulfadiazine

Dr. Eyles and Miss Coleman are from the laboratory of tropical diseases of the Microbiological Institute, National Institutes of Health, Public Health Service, and are stationed at Memphis, Tenn.

Table 1. Summary of screening tests with 2,4-diaminopyrimidines

Drug	Dosage (mg. per- cent in diet)	Mean days to death (controls)	Mean days to death (experi- ment)	Delay of death due to drug ¹	Proguanil equiva- lent ² <i>P.</i> <i>berghei</i>
5-(4'-chlorophenyl)-6-ethyl (DCEP)-----	8	7.3	10.8	+3.5(S)	200

5-(4'-nitrobenzyl)-6-methyl-----	250	6.8	7.4	+ .6	.7
Sulfadiazine-----	50	6.8	6.8	0	1.5
	500	7.3	12.2	+4.9(S)	-----

¹ In calculating this mean all animals still living on the 14th day are considered as having lived just this long; letter (S) indicates significant difference between test and control.

² From Falco and associates (1).

are included for comparison. DCEP and 2,4-diamino-5-(4'-chlorophenyl)-6-n-amyl pyrimidine were significantly active. DCEP was considered sufficiently effective to warrant further investigation, since several animals not only lived longer than the controls, but also survived indefinitely.

The dose-effect curve for DCEP is shown in the chart. The MED was calculated as 9 mg. percent in the diet (95-percent confidence limits, 15 and 5). This is the equivalent of about 18 mg./kg. per day (calculated on the basis of 4 gm. of food consumed per day). According to data in this laboratory, sulfadiazine has, in comparison, a MED of 40 mg. percent in the diet. Gram for gram, DCEP is more effective, but its therapeutic efficiency is much lower, as 9 mg. percent is close to the MTD, which was found to be 32 mg. percent; whereas, the MTD of sulfadiazine is at least 12 to 24 times the MED.

DCEP appeared to cure some mice; a number of animals survived until killed or challenged 42 days after the day of infection. Table 2 presents these data and data on survival until the end of the 14-day treatment period. The number of mice which survived for 14 days was only slightly smaller than the number surviving for 10 days. Of the 23 mice which survived 14 days, 9 were still living at 42 days. With one exception, all of the mice which died between the fourteenth and the forty-second day died within a week of the end of the treatment period. This was somewhat different from groups given sulfadiazine; post-treatment deaths in these mice occurred

frequently two or more weeks after the end of treatment (5).

In order to determine if the mice surviving 42 days were cured (free of organisms), four of the nine mice were killed, and suspensions of brain and liver tissue from each were inoculated intraperitoneally (i. p.) into two clean mice. One of the mice inoculated from one survivor died from toxoplasmosis in 6 days; none of the other mice developed the disease during a 42-day observation period.

To determine if surviving animals were immune to reinfection, five of the survivors were challenged with an i. p. inoculation of 20,000 *Toxoplasma* organisms on the forty-second day. Four of the mice died in the usual 7 ± 1 days, but one survived until the tenth day. The last finding may possibly have significance in indicating some degree of immunity.

None of the animals killed on the forty-second day showed any organisms in smears made from brain, liver, spleen, peritoneal fluid, and lung.

Table 2. Survival and possible cure after treatment with DCEP

Dosage (mg. percent in diet)	Number of animals	Survived 10 days	Survived 14 days (end of treat- ment)	Survived 42 days (cured?)
32 (toxic)-----	9	4	3	2
16-----	15	10	9	4
12-----	6	2	2	2
8-----	24	11	8	1
4-----	18	1	1	0
2-----	9	0	0	0
1-----	9	0	0	0

PER CENT OF MICE SURVIVING 10 DAYS

Dose-effect curve for 2,4-diamino 5-(4'-chlorophenyl)-6-ethyl pyrimidine.

Discussion and Conclusions

These findings add another chemical group to those known to be active against toxoplasmosis. They also illustrate an instance of parallelism between antimalarial and antitoxoplasmic activity. Experiments are now in progress to determine if sulfadiazine and 2,4-diaminopyrimidines act synergistically as in malaria therapy (2) and if pteroylglutamic acid (PGA) antagonizes their effect (3).

The investigation so far indicates, but does not prove conclusively, that DCEP is a curative drug in some instances. More animals must be subjected to subinoculation tests, and other animals must be observed for longer periods of time. Further tests must be made using large inoculums. In any event, the efficiency (ratio MTD/MED) of DCEP alone is so low (about 3 or less) that it is not likely to be a practical

drug in human toxoplasmosis although the different host may affect its action. If DCEP proves to act synergistically with sulfadiazine then it may be of practical importance in enhancing the effect of that drug. If it is antagonized by PGA, interesting hypotheses with regard to the physiology of *Toxoplasma* may be raised.

Summary

Screening of compounds for antitoxoplasmic activity showed two members of the 2,4-diaminopyrimidine group to have effect. The most active compound was 2,4-diamino-5-(4'-chlorophenyl)-6-ethyl pyrimidine. Defining the effective dose as the dose permitting 10-day survival, this compound had a MED of 9 mg. percent in the diet as compared with 40 mg. percent for sulfadiazine under identical conditions.

The efficiency of the drug was low, as the MTD/MED ratio was about 3 or less. The cure rate following 14-day treatment was also low since only 9 of 33 mice (27 percent) given doses higher than the MED survived for 42 days.

* * * * *

Since preparing this paper, it has come to the attention of the authors that Dr. W. A. Summers of the Indiana University Medical Center has tested some of the compounds reported in this paper with results parallel to those reported here. Dr. Summer's work will be separately published.

ACKNOWLEDGMENT

The drugs used in these experiments were obtained through the courtesy of Wellcome Research Laboratories, Tuckahoe, N. Y. The desirability of screening these compounds was pointed out to the authors by Dr. G. Robert Contney. Acknowledgment is due also to Jean Vaughan and Ernest Guy for technical assistance in obtaining data for this report.

International Tuberculosis Control Program

In a 4-year international tuberculosis campaign involving 22 countries on five continents, the United Nations International Children's Emergency Fund (UNICEF) and three Scandinavian relief agencies tested 37 million children and young adults and vaccinated nearly 17 million with BCG.

The Scandinavian associates—the Danish Red Cross, Norwegian Relief for Europe, and the Swedish Red Cross—started the work of tuberculosis control projects after World War II and were joined by the UNICEF in 1948. They have now withdrawn from the program after fulfilling their commitments.

Czechoslovakia, Poland, Hungary, and East Germany participated in the European phase of the program. Poland was highest in numbers of vaccinations with 2,535,026. Czechoslovakia was second, and East and West Germany, considered together, were third.

The UNICEF is continuing the international campaign and plans to test the entire child populations of Asia, Latin-America, and the Eastern Mediterranean countries. Five million children already have been tested in Ceylon, India, and Pakistan. The World Health Organization is responsible for the technical aspects of the program.

The results of the campaign will not be fully known until the children and young adults vaccinated have reached maturity. However, already there are some favorable indications in Poland, where very few of the persons vaccinated have contracted tuberculosis.

Staining *Treponema Pallidum* And Other *Treponemata*

By B. S. LEVINE, Ph.D.

The principles of staining necessary to obtain suitable results in the direct microscopic count of milk have been outlined in a previous publication (1). That study was originally undertaken to improve milk-film staining procedures. However, the principles discussed apply equally to other types of biological staining, and study has been made of the staining of spirochetes, especially those of the *pallidum* type.

A comprehensive review of the literature pertaining to the staining of *Treponema pallidum* was presented by Campbell and Rosahn (2), and recently DeLamater and others (3) have described a new modification of the Fontana staining procedure. Campbell and Rosahn classify all previously recommended procedures for staining *T. pallidum* into two groups. In the first group, the spirochetes are impregnated by a dye or a metallic ion and made visible against a pale background. In the procedures of the second group, the background is darkened by a material such as India ink or by an alteration in the method of illumination, as in the dark-field procedure. The value of the dark-field method of examination in the hands of an experienced person can hardly be over-

estimated as a rapid and reliable diagnostic aid. However, efforts to develop a quick and easy staining procedure for the demonstration of spirochetes, and especially of *T. pallidum*, have never abated.

Concerning the impregnation of spirochetes by dyes and metallic ions, the statements made by Campbell and Rosahn can well be repeated. These authors state: "At one time or another practically all the dyes utilized by the histologist have been employed in efforts to stain the spirochete. In all cases simple aniline dyes alone have not succeeded in staining the organism sharply, and only when a suitable mordant was employed was the stain at all reliable." Most staining procedures based on the mordanting principles are complex, time consuming, inconsistent in the hands of the same technician, and frequently result in complete failure in the hands of well-trained laboratory workers. Silver impregnation techniques, while apparently highly specific for spirochetes, are not adaptable to routine laboratory work. They appear to be best suited for tissues. In addition, as aptly stated by Campbell and Rosahn, "Silver impregnation techniques when applied to smears have for the most part resulted in atypical forms with marked changes in the regularity and shape of the spirals. . . ."

The Staining Procedure

Survey of the literature cited, personal interviews with research workers in this field, and visits to several venereal disease research labor-

Dr. Levine is a bacteriologist with the research and development branch of the Public Health Service Environmental Health Center in Cincinnati. This paper was presented at the general session of the meeting of the Society of American Bacteriologists on May 31, 1951, at Chicago, Ill.

atories and syphilis diagnostic clinics indicated the need for the development of a spirochetal staining procedure which could be used routinely in clinical and public health laboratories. Based upon experience with many spirochetal staining formulas and the principles of biological staining cited (1), a number of procedures for the preparation of spirochetal slide speci-

Figure 1. Trench mouth smear ($\times 3,300$).

mens and a number of staining solutions considered appropriate were prepared. Staining tests made led to the development of the following staining procedure.

Preparation of Smears or Films

The materials tested were: (1) culture suspensions of the following avirulent spirochetes—(a) Reiter's, (b) Nichols, and (c) the Kazan strain; (2) oral smears from persons known to harbor a variety of spirochetes; (3) suspensions of testicular material of rabbits experimentally infected with Nichols strain of *T. pallidum*; (4) suspension of testicular material of a rabbit experimentally infected with a strain of *Treponema cuniculi*; and (5) smears from clinical cases having genital lesions which were positive by dark-field examination. In all cases the material was spread thinly over an area approximately 1 cm. square, and dried in the air. The slides were then placed in a removable slide tray or a Coplin jar and defatted for 2 minutes or longer with U.S.P. chloroform, made acid-free with an excess of sodium or potassium carbonate. The slides were then drained and dried free from chloroform. They

were again submerged for 2 minutes or longer into another glass container filled with 95-percent ethanol or methanol likewise made acid-free by adding an excess of sodium or potassium carbonate. The slides were again drained and dried free of the alcohol.

Preparation of Stock and Final Stain Solutions

Staining of any of the previously mentioned spirochete-containing materials can be accomplished either with crystal violet or with basic fuchsin. The use of certified dyes is recommended. Prepare: (1) a 2.5-percent solution of sodium or potassium carbonate in distilled water and (2) a 1-percent solution of crystal violet or of basic fuchsin in distilled water. These should be labeled "Stock Solutions." They can be kept indefinitely without serious deterioration.

For the preparation of the final staining solution, place 89 ml. of distilled water in a clean glass beaker. Add to this 1 ml. of either the potassium or sodium carbonate stock solution. Mix well. To this add rapidly 10 ml. of either

Figure 2. Culture of avirulent Reiter's spirochete ($\times 1,500$).

crystal violet or basic fuchsin stock dye solution. Mix well. The final stain-solution should not be prepared until the slides are ready for staining. Staining should be done as soon as possible after the final stain-solution has been prepared. It is recommended that after 4 to 6 hours a new final stain-solution be made. The addition to this final staining solution of sodium bicarbonate in varying amounts tends to stabilize it, so that it can be used for a longer

period of time. Such stabilization of the final staining solution as indicated thus far appears to add nothing to the spirochete-staining properties of the solution.

Staining of Slide Specimens

Place the previously prepared slide specimens in a Coplin jar or removable slide tray and MacCallum type of staining dish. Fill the staining dish with the final crystal violet or basic fuchsin stain-solution until slides are completely submerged. Two minutes is a sufficient time interval for proper staining. Leaving the slide specimens in the final stain-solution for a longer period will not cause overstaining. It is, however, considered best to adhere to the 2-minute staining interval. Remove the slides from the staining solution one at a time or, if a tray is used, remove the entire lot and rinse lightly in a beaker or other suitable glass dish containing tap water until it is judged that excess stain has been removed. Drain, air dry, and examine microscopically.

It was observed on numerous occasions that the presence of phosphates in the preparation material appears to interfere with the proper staining of the finer forms of the spirochetes. It is therefore suggested that extraction of testicular material be made with distilled water or with isotonic saline.

Under the microscope, treponemata, especially *T. pallidum*, stained with basic fuchsin appear to be very slender and to have a smooth and even surface. Crystal violet imparts to the spirochetes a greater thickness and a certain coarseness of surface. With either stain, however, the morphology of the spirochetes remains unaffected. For this reason it is rather easy, after some experience, to differentiate *T. pallidum* as it occurs in rabbit testicular or clinical material from the avirulent types as presented by the cultures previously mentioned. Differentiation is not so simple with oral smears, for in these, on occasion, spirochetes which only a few microscopists can differentiate with any degree of certainty are observed. Clinical syphilologists say that in the case of suspicious genital lesions the proper decision can be arrived at with ease, as it is generally believed that spirochetes other than *T. pallidum* do not invade the deeper tissues.

Precautions

Attention is invited to the following consideration: The standing procedure described takes into account certain principles of adsorption. Each step outlined is designed to meet certain specific conditions of such adsorption. It is therefore recommended that the procedure be adhered to as closely as possible. It is especially recommended that the prepared slide specimen be submerged into the final dye solution edgewise, as previously described. Placing the slide specimen horizontally on a staining table and flooding it with the final dye solution is definitely not recommended.

Advantages of the New Staining Procedure

The advantages of the staining procedure described are as follows: No mordants are required; no heating of the specimens or of any of the solutions is necessary; the reagents used are commonly found in any public health or clinical laboratory; staining can be accomplished within 5 to 10 minutes; a trayful of slide specimens takes no longer to stain than a single specimen; the tolerance range with regard to the prevailing pH of any of the solutions is rather wide, thus eliminating the need for unusual care in the staining process; the slides can be destained and restained any number of times (as will be described later) without in any way affecting the original staining properties or the morphology of the spirochetes. Permanent mounts can be made or the specimens can be destained and restained if fading has occurred, or, if it is desired, the same slide may be studied as stained first with the crystal violet and then with the basic fuchsin, or conversely. Other advantages of this staining procedure may make themselves evident to the laboratory worker as he gains experience with it. What has been specifically mentioned is sufficient to indicate that the staining procedure described appears adaptable to routine laboratory procedure.

To destain and restain a specimen, treat the slide as if it had not been stained. First, defat in the acid-free chloroform; this will remove the immersion oil and will almost completely destain the specimen. Second, submerge the

National Program for Interstate Milk Shipments

By LEONARD A. SCHEELE, M.D., and HARRY G. HANSON, B.S., M.S.E.

As a background for the views of the Public Health Service on a national program for interstate milk shipments, we would like first to describe briefly the responsibilities of our organization in the broad field of milk sanitation. Then we shall outline for you the major problems, as we see them, which necessitate the establishment of a cooperative program for the certification of interstate shippers of milk.

The Public Health Service has a long-standing and dual interest in milk and milk products. These products occupy a unique position in human nutrition and they play an important role in the transmission of infectious diseases to man.

The nutritional importance of milk and milk products is one of the foundation stones upon which the dairy industry has been built. Adequate amounts of milk and milk products are not only essential to the maintenance of good

health in all age groups, but in these days of high costs of living, these products are still among the best buys in terms of food value per dollar of expenditure. Thus, the Public Health Service, along with other health agencies, has long advocated—and continues to advocate—the increased consumption of milk and milk products.

Early PHS Investigations

To make possible the increasing consumption of milk in our growing urban population, the Public Health Service has also been concerned with the safety of market milk. The interstate quarantine responsibilities of the Service as early as 1893 directed our attention to the role of milk in the transmission of infectious diseases. Early bacteriological investigations made by the Service led to the establishment in 1923 of an Office of Milk Investigations, which had the responsibility of investigating milk-borne outbreaks of disease, recommending methods for their prevention and control, and establishing standards for the sanitary quality of milk and milk products served aboard trains and ships operating in interstate commerce.

These investigations, as well as more recent studies, were conducted in cooperation with the dairy industry and State and local health agencies. One result of these scientific studies was the conclusion that a safe milk supply for the public required the elimination of disease in dairy herds, the application of sanitation techniques to milk production, and the effective pasteurization of milk and milk products.

The first World War gave significant impetus to improved sanitation in this country. At that time, we experienced our first crisis in public

Dr. Scheele is Surgeon General and Mr. Hanson is Executive Officer of the Public Health Service, Federal Security Agency.

This statement was read by Mr. Hanson in a symposium before the Fifth Annual Meeting of the Dairy Products Improvement Institute, Inc., in New York, January 17, 1952. At the same time, "The Purpose, Plans, and Progress of the National Conference on Interstate Milk Shipments" were discussed by J. L. Rowland, M.P.H., chairman of the conference and director of the bureau of food and drugs of the Division of Health of Missouri; and C. J. Babcock of the Production and Marketing Administration of the Department of Agriculture spoke on "Standards for Grades of Milk and Cream for Manufacturing Purposes."

health with respect to increased mobility of population and concentration of military personnel in areas lacking modern methods of sanitation and milk control. A review of milk control regulations then in force revealed that many States and municipalities had no such regulations. Among those that had adopted milk control laws and regulations, there was a lack of uniformity in approach and standards which negated the possibility of a safe and acceptable milk supply for the Nation as a whole.

Cooperative Development of Standards

These findings clearly indicated the need for practical and uniform regulations, based upon sanitary science and veterinary medicine, which could be adopted and enforced throughout the Nation. The Public Health Service therefore drew together a group of authorities in the field—whose institutional connections included State and local health agencies, the dairy industry, universities, and State departments of agriculture—to assist in the development of a municipal ordinance for milk sanitation. In 1932 a National Milk Sanitation Advisory Board was appointed and the Public Health Service has maintained such an advisory body to the present day, with the addition of experts in other fields of food sanitation.

With the advice of its consultants and with the active cooperation of the States, cities, and the dairy industry, the Public Health Service developed in 1923 a standard ordinance for voluntary adoption. Since that time, there have been nine revisions of the Milk Ordinance and Code Recommended by the United States Public Health Service, including that of 1952, which will be published in a few months.

Each revision of the recommended ordinance and code has been accomplished with the active cooperation of our advisory board and representatives of the groups who aided in the original development. We emphasize the Public Health Service's method of cooperative action because there is a tendency nowadays to assume that any action by any Federal agency is designed to bring about Federal control and regulation. The long-established policy and practice of the Public Health Service has been to bring about the solution of broad problems af-

fecting the Nation's health preferably by the collection of scientific data, consultation, technical aid, and cooperation, rather than by undertaking the enforcement of regulations ourselves.

We would like to add that this has been our policy and practice even when Congressional legislation has given us clear regulatory and enforcement authority—as in the case of the control of biological products and of interstate quarantine. Up to the present time we have found this approach both economical and effective. The public, as well as the Federal Government, the industries involved, and the State agencies, have been spared the costs and delay of regulatory hearings and court action. And in each instance, there has been protection for the public and unabated progress in the development, distribution, and sale of safe and potent biological products and in the sanitary quality of foods and water served on interstate carriers.

Sanitary Control of Market Milk

The Milk Ordinance and Code Recommended by the Public Health Service was prepared for voluntary adoption by local governments. What has been the effect of this proposal upon the sanitary quality of market milk consumed in the United States?

At the present time, the ordinance and code has been adopted by more than 1,500 municipalities and 387 counties in 38 States and Alaska. It is also the basis of milk sanitation laws or regulations in 34 States, Alaska, and Hawaii. Eleven of these States and the two Territories enforce the code state-wide. Included in this milk sanitation program are 55 cities with populations of over 100,000, and 38 with populations of 50,000 to 100,000. According to data from the 1950 United States Census, more than 60,000,000 persons are thus protected by the milk ordinance and code which was first developed jointly by the dairy and related industries and Federal, State, and local health agencies nearly 30 years ago.

In 1938, milk-borne outbreaks constituted one-fourth of all disease outbreaks due to infected foods and polluted water. The most recent data show that milk and milk products are

responsible for only 3½ percent of such reported outbreaks. Today, more than 90 percent of the market milk consumed in the United States is pasteurized—a phenomenal development over the past 30 years.

Public health agencies do not claim that the long-term cooperative program in milk sanitation has been the sole factor in the improvement of the Nation's milk supply. But there is good evidence that this joint effort of the health agencies and the industries has been and is a major and decisive factor. The reduction in the incidence of milk-borne diseases and in the mortality from these causes over the past 30 years has been an outstanding accomplishment. Many groups have contributed to this achievement. Public health and agricultural agencies, the dairy and related industries, the medical and veterinary professions, educational institutions, and an enlightened public all share the credit.

Constant Supervision Needed

Despite the progress that has been made, we must continue our efforts to protect our market milk supplies and milk products. Constant vigilance is as essential in this area as in the maintenance of safe water supplies. The fact which we must keep ever in the front of our thinking, our planning, and our operations is that milk is an efficient medium for the growth of pathological organisms. A safe milk supply demands effective sanitation techniques at every stage of production, processing, and delivery.

This is not to say that effective sanitation today is identical in every respect with that of 30 years ago. The results of scientific research and technology have made available new types of equipment and less burdensome methods. The Public Health Service, the related industries, and many State and local agencies have recognized and stimulated technological progress in this field. The numerous revisions of the ordinance and code testify to this determination on our part and that of our advisers to keep pace with new developments and thus to give the public the benefits of scientific progress.

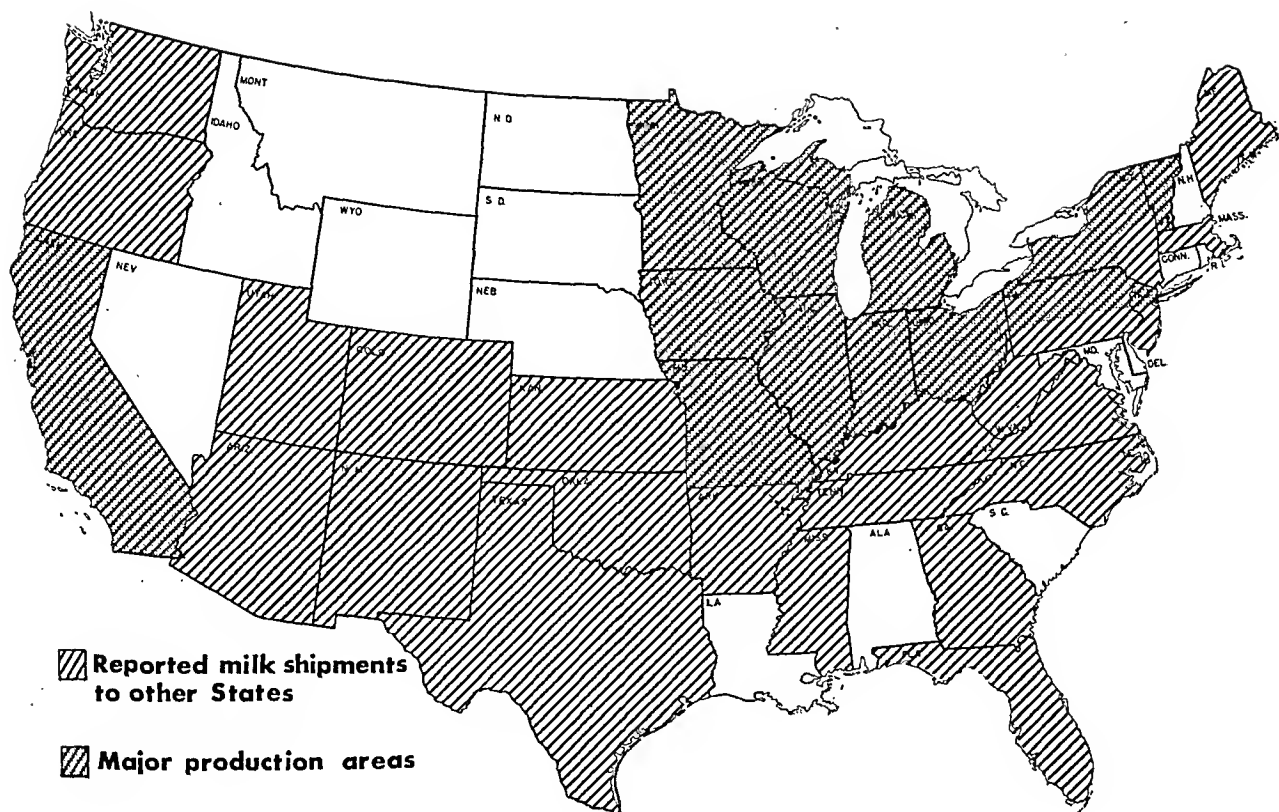

It is true that not all of the old problems in milk sanitation have been solved. Indeed, new ones are constantly coming to light. The control of brucellosis is still a major problem. The recent demonstration that Q fever organisms exist in some dairy herds requires that intensive research be directed to the mode of transmission of this disease to man. New methods for processing, packaging, and marketing milk and milk products are constantly being introduced. If these methods are to be widely adopted, both consumers and producers need the assurance of careful scientific studies upon which to base the needed safeguards.

Use of Chemicals and Antibiotics

There is a wide gap between our precise knowledge and the safe use of chemicals as preservatives, or of antibiotics in the treatment of dairy herds, or of insecticides in the eradication of disease-carrying flies, mosquitoes, and so on. In these situations, medical and related research has a big job to do to determine the cumulative effects of small amounts of such substances in milk as consumed by the public.

We should like to point out, however, that all of the agencies and industries involved are faced with a dilemma. Failure to use the necessary amounts of antibiotics and insecticides would certainly expose the public to serious risks of infection with the dysenteries, streptococcal and staphylococcal infections, and other dangerous diseases which may be transmitted by the milk of infected herds or by insects. On the other hand, some health authorities have raised the question of possible toxic reactions to small amounts of DDT in milk, for example; or of resistance in children to antibiotics through the ingestion of small amounts in the milk of animals treated with such drugs.

Man's environment has always presented risks to his health and safety. The question today is whether the use of chemicals—both in the war against communicable disease and in the production and distribution of a safe, ample, varied food supply for every part of the country—presents serious risks to public health; or whether uncontrolled sources of infection or reductions in needed food supplies present more serious risks than the use of chemicals.

The Public Health Service is aware of the dilemma. Through our laboratory and field research centers, we are now developing an intensive research program directed to studies of the chemical environment as it affects human health. Many of the problems to be investigated concern the dairy industry and the official agencies, as well as the public. Our view is that scientific research can provide the answers which will make possible the application of valuable chemical techniques without significant risk and with great benefit to the public.

The Public Health Service works—and always has worked—on the principle that new techniques recommended to the public for better health or for greater health protection must be not only effective but safe. The basis of assurance is thorough, multidisciplinary research in pertinent experimental, clinical, and epidemiological fields. We consider that such investigations are part of our general responsibility for the public health.

Even so, we are bound to admit that no method or agent used in medical and public health practice is completely free of risk. Exceptions to demonstrated findings of safety and

effectiveness are bound to occur. Both private physicians and health agencies are obliged to take calculated risks in discharging their responsibilities to society. Their decisions must be based upon scientific determinations that the risk is minimal and that it is outweighed by demonstrated benefit to the individual patient or the public.

Interstate Milk Shipments

The technical problems in milk sanitation which we have been discussing are accompanied by another larger problem, namely, the interstate shipment of milk and milk products. A practical solution for it has been proposed.

Until comparatively recent years, the volume of market milk and cream shipped in interstate commerce was small. It created no special problems except for large metropolitan centers such as New York. The public demand for these products, however, has exceeded the local supply in many areas, and throughout the past 10 years the needs of the armed forces also have increased markedly.

Interstate milk shipments today indicate that the problem is national in scope and volume.

Shaded States report receipt of milk shipments from other States

At present—as shown by the maps—32 States, the District of Columbia, and Alaska import fluid milk and cream for public consumption, and 34 States are exporters.

Estimates from 40 States show that a minimum of 13,000,000 pounds of milk and cream are shipped interstate—daily. Shipments include both pasteurized milk and cream in bottles and cartons, and raw milk in bulk for pasteurization in importing localities.

Prior to the development of refrigerated transport, the production and marketing of milk could be considered almost exclusively a local affair. Each locality produced enough milk to meet the local demand except during brief seasonal shortages. The development of local milk sheds for each community, with local controls to insure a clean and wholesome product, was the pattern established to meet the limited demands of that period.

Under present conditions, this pattern is not adequate to meet the demand for milk and milk products in metropolitan centers and milk-deficient areas. Industrialization, increases in

population, accelerated urbanization, and related factors all have contributed to the change. The importation of market milk and cream across State lines is an essential element of the Nation's economy. The public health problem involved is to afford the authorities of importing areas reasonable guarantees as to the safety and wholesomeness of imported milk and milk products.

The Multiple Inspection Problem

State and local governments have the legal right and authority to satisfy themselves that milk received from outside their jurisdiction shall be safe. Officials of importing States and municipalities have usually taken the position that imported milk should meet sanitary requirements identical with those imposed upon local producers. As a result, many milk control agencies have adopted the practice of sending their own inspectors to the States from which the shipments come.

Inspection at the source creates a great deal

of difficulty in the interstate shipment of milk. In the first place, the regulations of the shipping areas may differ widely from those of the receiving municipalities. Second, it is not uncommon for numerous municipalities to purchase milk from the same interstate shipper. As a result, multiple inspections of the same supply by sanitarians from many different jurisdictions impose an unwarranted burden upon producers. Producers resent these confusing and troublesome practices and they are interested in finding a way to eliminate them.

It is easy to see why. The dairy farmer—the dairy industry in fact—knows that the requirements essential to protect the consumer against disease are practically the same regardless of the geographic area involved. Hence, he cannot understand why the requirements of different local jurisdictions differ or contradict each other. He cannot understand why health authorities of one jurisdiction should not accept the results of inspections by health authorities of another.

The Public Health Service holds the same view as to the desirability of uniform regulations and reciprocity in the inspection of milk. We have long felt that the first step toward a successful interstate milk shipment program must be acceptance by all concerned of common criteria for the evaluation of the sanitary quality of a milk supply.

There is no question that a State or community has the right to inspect at the source the milk and milk products it is to receive. But it is our view that some less cumbersome, less expensive, and more efficient method can be developed which will meet universal approval and will benefit all interests. Multiple inspections are expensive for both shipping and receiving areas and sometimes absorb tax funds which are urgently needed for other health purposes. The maintenance of multiple standards by milk producers may also require unnecessary expenditures which increase the cost of milk to the consumer.

It is doubtful also that infrequent inspections by sanitarians from distant areas provide more than superficial protection, since such inspections are not followed by routine control measures. In this connection, the health authorities of some shipping communities do not assume

responsibility for the sanitary supervision and control of surplus milk produced under their jurisdiction on the ground that it is not for local consumption.

Because of the expense involved, many importing States and municipalities cannot afford to send their own men to the State of origin. The alternatives, as the officials in the importing areas see it, have been to accept milk of unknown or questionable sanitary quality, or to refuse permission to import milk even though it is needed to provide adequate supplies for their communities. Some authorities have refused to accept any milk from beyond the limits of their own routine inspection; although during periods of extreme shortage they may permit the importation of milk not subject to any sanitary control.

Health Rules as Trade Barriers

Obviously, there are important economic as well as health factors involved in the shipment of milk from surplus to deficient areas. Without attempting to discuss the economics in detail, we do wish to emphasize that the invocation of health requirements as a means of solving problems of trade and commerce is unwarranted. This practice has been increasing in recent years, and has given rise to serious interference with interstate and even intrastate commerce. It has not afforded greater health protection and has actually made increased consumption of milk and milk products more difficult for the lower-income families in some areas.

The technique most commonly used is to insert into local milk sanitation regulations restrictive requirements that can be met only by local producers and processors. Most such restrictions have little or no public health significance, and are even difficult to guise as public health requirements.

As an example, some municipalities forbid the sale of any milk that is not pasteurized within so many miles of the center of the community. The assumption is that all milk pasteurized beyond that point is not safe to drink, since the city does not wish to inspect it. The purpose of these arbitrary requirements is, of course, to exclude all outside milk re-

ardless of its wholesomeness, thus preventing competition.

The growth of these trade barriers has been so rapid, and their effect on interstate milk shipments so great, that in 1950 the United States Supreme Court and a committee of the United States Senate both dealt with the matter.

Supreme Court Ruling

The Supreme Court, during its October 1950 term, ruled that a city could not adopt discriminating health regulations which act as trade barriers against interstate commerce. Such action, the Court stated, could not be taken, even to protect the public health and safety, providing that reasonable nondiscriminatory alternatives were available to afford such protection. The Court then pointed out that two reasonable alternatives exist. A city may rely upon its own officials for inspection of distant milk sources; or it may rely on inspections made by health authorities at the source, as provided in section 11 of the Milk Ordinance and Code Recommended by the Public Health Service. This section establishes reciprocity as a basis for acceptance of outside milk, and defines the criteria which must be met.

The Senate Committee on Agriculture and Forestry, through a subcommittee, held public hearings to determine the cause and effect of restrictive regulations and reported, August 1, 1951, that the movement of milk in interstate commerce was being impeded, and indicated that a solution must be found. The committee stated that it was not yet prepared to recommend Federal inspection, but it endorsed a second solution, namely, for the Public Health Service to increase its efforts to develop a cooperative program with the States for the certification of interstate milk shippers.

The Public Health Service concurs heartily with these recent recommendations of the Supreme Court and the Senate Committee. We hope that health agencies everywhere will resist local groups who promote the practice of adopting health regulations in order to set up trade barriers. It is also hoped that the Supreme Court decision will be a deterrent to the future incorporation of trade barriers in local

milk legislation, and that such obstacles to the free movement of milk will be removed.

An Interstate Certification System

Throughout the past 10 years, State and local health authorities, agricultural officials, and the dairy industry have intensified their demands for a plan for certification of interstate milk shipments on which importing areas may rely with confidence. The Food and Drug Administration and the Department of the Army have endorsed the idea. The Association of State and Territorial Health Officers, the American Public Health Association, and the Conference of State Sanitary Engineers have formally requested the Public Health Service to develop such a plan, in cooperation with the States. These groups have expressed the opinion that, since the problem is an interstate one, some degree of coordination and assistance by the Public Health Service is required.

Since 1946, the Public Health Service has been receiving more and more requests to make inspections of interstate milk supplies. For example, in 1949, State and local milk control agencies requested the Public Health Service to inspect the supplies of more than 170 individual shippers drawing milk from more than 40,000 dairy farms. The Service, with a very limited budget for all its milk and food sanitation activities, was not in a position to honor all these requests, nor did we feel that it was our place to do so. These requests emphasize the need for a system of certification based on adequate sanitary control and inspection by the State in which the milk is produced.

Conferences on Interstate Shipments

Early in 1950, representatives of 11 Midwestern State health departments met in Chicago to determine what action could be taken to establish such a program on a nation-wide basis. Subsequently, two National Conferences on Interstate Milk Shipments were held in St. Louis. Representatives of agriculture departments and health departments from 26 States attended, as well as representatives of the dairy industry and the Public Health Service. A third conference is scheduled for June 10-12 in St. Louis.

The plan and procedures as developed by these conferences incorporate the views of the majority of the receiving and shipping States.

The elements of the program in which the participation of the Public Health Service is specifically requested may be summarized as follows:

1. Ratings of the milk sheds of interstate shippers are to be made periodically by the State of origin in accordance with the uniform milk sanitation rating procedures developed by the Public Health Service. The results of such ratings are to be reported to the Public Health Service for certification.

2. Frequent spot check surveys are to be made by Public Health Service milk specialists of the inspection, laboratory, and rating procedures of each State participating in the program. Such spot checks are necessary to protect receiving areas against laxness on the part of milk sanitation authorities in shipping areas.

3. Lists of interstate shippers, as rated by the shipping States, are to be published and widely distributed semiannually by the Public Health Service. Between publication dates, State ratings as reported to and certified by the Public Health Service are to be forwarded to receiving areas as supplements to the published list.

4. The Public Health Service is to assist the States, when requested, to develop and improve their milk control programs, standardize procedures, and train State, municipal, and industrial inspectors and laboratory personnel.

5. The Milk Ordinance and Code Recommended by the Public Health Service is to be used as the basic standard for evaluating or rating interstate milk supplies. As stated earlier, this ordinance has been incorporated in the milk sanitation regulations of 32 States and 2 Territories.

Some States have already initiated the program on a limited basis. Ratings submitted by these States have been published by the Public

Health Service, and include the names and ratings of 182 shippers located in 17 States and the District of Columbia.

The agreements reached and the decisions made by the States themselves at the two National Conferences on Interstate Milk Shipments represent, in our opinion, the most progressive step taken to date toward solution of the health problems involved in interstate milk shipments. The Public Health Service endorses the national program proposed by these conferences, and, within the limits of our budget, we propose to assume the responsibilities which its full implementation would place upon us. Obviously we cannot take on all of these duties immediately without increasing our staff.

Need for Industry Participation

If it is to accomplish its purpose, the proposed national program for interstate milk shipments must have the endorsement of all regulatory agencies, and of the producers, processors, and distributors of milk and milk products. It needs the support of this Institute and the members of this audience. It needs your active, voluntary participation. We believe that such participation is to your advantage, and is certainly within the pattern of conscientious, public-spirited service which has always marked the operations of the dairy industry.

Many unforeseen problems will arise which will have to be worked out on the basis of experience. You can help work them out, help modify the system when and as it needs modification, and you can give health and agriculture authorities the benefit of your organized experience and advice. The proposed program presents another opportunity for the dairy industry and health agencies to extend their close working relationship in their common purpose of furnishing a high quality milk supply for the improvement of public health.

Milk Sanitation Honor Roll for 1950-51

Sixty-four communities have been added to the Public Health Service "honor roll" of safe milk communities, and 24 communities on the previous list have been dropped. This revision covers the period from January 1, 1950, to December 31, 1951, and includes a total of 251 cities and counties.

Communities on the "honor roll" have complied substantially with the various items of sanitation required by the Milk Ordinance and Code Recommended by the United States Public Health Service. The State milk sanitation authorities concerned must report this compliance to the Public Health Service. The rating of 90 percent or more, which is necessary for inclusion on the list, is computed from the weighted average of the percentages of compliance. Separate lists are compiled for communities in which all market milk is pasteurized and for those in which both raw and pasteurized milk is sold.

The Public Health Service Milk

This compilation is from the Division of Sanitation of the Bureau of State Services, Public Health Service. The previous listing, with a summary of rules under which a community is included, were published in Public Health Reports, August 24, 1951, pp. 1086-1090. The rating method was described in Public Health Reports 53: 1386 (1938). Reprint No. 1970.

Ordinance, which forms the basis for the milk ratings, is now in effect through voluntary adoption in 387 counties and 1,535 municipalities. These represent increases of 18 and 43, respectively, in the past 6 months. The ordinance has been adopted as regulation by 34 States and 2 Territories. In 11 States and the 2 Territories it is in effect State-wide.

Although the ratings do not represent a complete measure of safety, they do indicate how closely a community's milk supply conforms to the standards for grade A milk as stated

in the Public Health Service Milk Ordinance. High-grade pasteurized milk is safer than high-grade raw milk because of the added protection of pasteurization. The second list, therefore, shows the percentage of pasteurized milk in a community.

Although semiannual publication of the list is intended to encourage communities operating under the Public Health Service Ordinance to attain and maintain a high level of enforcement of its provisions, no comparison is intended with communities operating under other milk ordinances. Some communities might be deserving of inclusion, but they cannot be listed because no arrangements have been made for determination of their ratings by the State milk sanitation authority concerned. In other cases, the ratings which were submitted have lapsed because they were over 2 years old. Still other communities, some of which may have high-grade milk supplies, have indicated no desire for rating or inclusion.

NOTE: In these communities the pasteurized market milk shows a 90-percent or more compliance with the grade A pasteurized milk requirements and the raw market milk shows a 90-percent or more compliance with the grade A raw milk requirements of the Public Health Service Milk Ordinance and Code.

Note particularly the percentage of milk pasteurized in the various communities listed. This percentage is an important factor to consider in estimating the safety of a city's milk supply. All milk should be pasteurized or boiled, either commercially or at home, before it is consumed.

Tuberculosis Control in India

A new training center with modern equipment for tuberculosis control and treatment is to be opened in New Delhi.

WHO is providing an international team, a bacteriologist, an epidemiologist, a laboratory and X-ray expert, and a public health nurse. A local team of these specialists is also being provided by the Tuberculosis Association of India.

A mobile unit provided by the United Nations International Children's Emergency Fund for mass radiography has been used to examine 16,000 of the 27,000 inhabitants of the town of Faridabad, and 4,000 staff members and students in the Delhi hospitals and other institutions.

Training in tuberculosis control will include lectures and practical work in the laboratory and clinic, and in the homes of the patients. The program will (1) determine the exact extent of the tuberculosis situation in urban and rural communities, (2) protect young people through BCG vaccination, and (3) continue and expand home treatment and supervision of patients unable to go to sanatoriums.

The center will be an extension of the existing clinic of the Tuberculosis Association of India in the Irwin Compound and under the direction of Dr. B. K. Sikand.

Another training center with international assistance is operating in Trivandrum. A third center is expected to open in Patna, the WHO regional office for South East Asia reports.

Ideas

IDEAS are for you and from you. In this section we want to report on new techniques and ways of doing things—new ideas in public health practice. The emphasis is on method, procedure, tools, concepts, and the practical solutions to everyday problems: new twists and adaptations, for example, on maintaining two-way communication between the people we work with; on records systems and stock control; on epidemiology, program planning, and budget control; on assembling, timing, conduct of prenatal classes, and follow-up of school health examinations . . . the list has no end. We are looking for ideas—large or small—that have helped you and might help others in health departments, hospitals, voluntary health agencies, schools, and so on. If you feel that a place of exchange such as this will be useful, let us hear from you—with ideas.

—THE EDITORS

County PHN Boards

MINNESOTA. Down-to-earth ideas on how to make a county public health nursing advisory board realize its full potential in community health are summarized in a manual of the State Health Department. The boards are part of county government. Members include a commissioner, the superintendent of schools, the health officer or a physician, usually a dentist, and several other "residents of the county."

The manual points up the responsibilities of the board in the administration of public health nursing services and in interpreting health needs and programs to the community. It discusses the board's organization and function (a draft constitution is included) the recruiting of a nurse, and what to do while a vacancy interrupts services. Included are practical ideas of how to help the nurse with her job and how to go about program planning. On-the-job training, work with student and practical nurses, and the importance of clerical assistance are stressed.

Cardiac Course for GPs

NEWARK, N. J. For the second year general practitioners are being given an opportunity to become familiar with the newer knowledge and techniques of early cardiac case finding. The program began at St. Michael's Hospital in 1950. Announcement of the course resulted in 600 applications, although facilities permitted only 75 participants. The current course has 81 students selected from the original applicants.

The course consists of 20 full-day sessions, each with a 2-hour lecture plus ward rounds and clinics. Groups of seven physicians were given special training sessions in fluoroscopy, electrocardiography, and pathology. For physicians who exhibited unusual interest, additional special courses have been provided.

Traveling expenses are borne by the physicians, who also pay a \$5 fee. Students were selected on a geographic basis and it has been observed that those having to come the greatest distances are the most faithful in attendance. Many physicians have remarked on the value of the course to their practice of medicine. A number have noted that their prestige has been raised in the eyes of their patients. To aid in explaining the absence of physicians from their communities a day each week, local press announcements are contemplated.

From the 1950 group, six physicians are now contributing their

services to heart clinics, where the attendance has greatly increased because of the greater number of referrals from physicians from all parts of the State.

Staff members active in developing this course included Drs. Nicholas Antonius and Harrold Murray, presidents-elect of the Essex County and of the New Jersey State Medical Societies, respectively, and Dr. Bernard O'Connor. The work is actively supported by the New Jersey State Department of Health, Dr. Daniel Bergsma, commissioner, and Dr. Marion R. Stanford, chief of the section on heart diseases.

"Search" for News

CALIFORNIA. "Issued in the interest of Public Health by your local tuberculosis association" is *Search Magazine*, journal of the California Tuberculosis and Health Association. It appears monthly in news magazine style and reports in text and pictures (and in two colors) the health developments in California and the West.

A recent issue (see reproduction of cover) told the story of "bloody 99," the Sacramento-to-Los Angeles highway with 211 fatalities and 2,682 casualties in 1950; reported on the December clinical session of the American Medical Association; recorded in pictures (from San Diego)

the work of the public health nurse; discussed malpractice; commented on the aging population and the needs of children; and reported on pneumoconiosis from diatomaceous earth, as well as other health news of the month.

Search, first issued in June 1951, is directed by an editorial board of 10 members including 4 physicians. It was conceived to present health news to both physicians and non-medical health workers. Of the circulation of nearly 30,000 copies, more than 16,000 go to physicians.

Civil Defense Nursing

MARYLAND. The experience of nurses who attended an institute on nursing aspects of atomic warfare in Rochester, N. Y., has been drawn upon in developing a training program in Baltimore and outlying counties. With the help of the nurses who attended the advance course, the State health department developed, in manual form, a suggested training course. So far, some 3,000 professional nurses have received initial civil defense training. Included are many inactive nurses as well as those currently employed in industry, hospitals, private duty, public health, and as student nurses.

Rabies Control

VIRGINIA. Working from a 1948 ordinance requiring vaccination of all dogs, Pittsylvania County has cut reported rabies cases from 38 to 1 in a single season. Public health clinics for vaccination were set up at 91 stations. Printed placards with clinic schedules were posted.

The Virginia Department of Health purchased a well-tested vaccine in bulk, and distributed it to veterinarians locally. They in turn repaid the State out of clinic fees of 75 cents per dog. Certificates of vaccination were provided dog owners by the veterinarians. During the program, uncontrolled dogs were taken into custody, and strays were destroyed.

On the Trail

ATLANTA. The cartoon strip technique is being used to explain technical sewage treatment processes to people without technical training. It is the work of Ed Dodd, creator of the comic strip "Mark Trail."

He has done a series of pictures in which Mark, his young friend Scotty, and their dog Andy are shown through a sewage treatment plant by an engineer. In a combination of drawings and readable text, Mr.

Dodd makes the step-by-step process of sewage treatment clear to adults and young people alike, without sacrifice of technical accuracy.

The sequence reproduced here appears in a new 16-page full-color cartoon book, "The Fight to Save America's Waters," drawn as a public service by Mr. Dodd. The booklet is available through State water pollution authorities.

Mongoose Rabies in Puerto Rico

By ERNEST S. TIERKEL, D.V.M., M.P.H., GUILLERMO ARBONA, M.D., M.P.H.,
ALFONSO RIVERA, D.V.M., and ABEL de JUAN, M.D., M.P.H.

Rabies has been classified into two epidemiological types, the sylvatic or campestral type in wildlife and the disease as it is found in domestic dogs (1). In certain rural areas where rabies is enzootic, this epidemiological differentiation may not always be so discrete. The factors which influence the presence of both types simultaneously in a given area are the amount of contact between wild species and domestic dogs, the relative population sizes of both groups, and the immunity level of the domestic dog population.

Although the disease in dogs is still the principal rabies problem in most countries of the world today, mass canine immunization practices and other effective measures have brought about increasing control and eradication. Success with dogs has focused attention on the importance of various species of wild fauna in the spread and transmission of the disease.

In the Americas, rabies has been diagnosed sporadically in practically every kind of susceptible wild animal. In the United States, the principal large-scale sylvatic vectors of the disease have been the fox, genus *Vrocyon*; the skunk, genus *Mephitis* and genus *Spilogale*; and the coyote, *Canis latrans*. In South America, Central America, Trinidad, and Mexico, the

vampire bat, *Desmodus rotundus*, is an important transmitter of rabies.

The first major outbreak of rabies in an area of the Western Hemisphere, attributed to the Indian mongoose, *Herpestes javanicus*, is presented in this report.

History of Rabies in Puerto Rico

Information on the early history of rabies in Puerto Rico is restricted, for the most part, to the laws for controlling the disease. The first edict, issued in 1841, ordered owners to kill immediately any animals showing signs of hydrophobia or any other contagious disease (2-4). This law was reprinted in 1874 after an outbreak of rabies in Bayamon, and in 1875

The Indian mongoose, *Herpestes javanicus* (family Viverridae), is a small carnivore, with a body 14 to 17 inches long and a tail 11 to 13 inches long. It averages about 1.5 pounds in weight. Its hair coat varies from brindle to tan-gray in color. An extraordinarily wily animal, its ferocity is matched only by its speed of movement, and it is famous for its ability to attack and overcome snakes, even the poisonous cobra in its native India. Mongooses are largely migratory in habit and have no specific home range. The average daily foraging range is estimated to be one-eighth to one-fourth of a mile (11). In its daily movements it prefers natural runs which are fairly well covered by overgrown brush.

Dr. Tierkel is from the veterinary public health branch of the Communicable Disease Center, Public Health Service, Atlanta, Ga. Dr. Arbona and Dr. de Juan are from the Puerto Rico Health Department's division of public health and Dr. Rivera, from the veterinary division of the Puerto Rico Department of Agriculture, San Juan, P. R.

after several cases were found at different places on the island.

In 1896, the occurrence of two human cases of rabies motivated the establishment of a histochemical-bacteriological institute at the city of Mayaguez (5). After the American occupation, general order No. 221, dated December 19, 1899, contained the following: "Any animal suspected of having hydrophobia should be killed instantly and burned or buried in a deep grave" (2).

From 1910 to 1949, 21 cases of rabies diagnosed by laboratory examination of suspected specimens (table 1) were reported by the Puerto

³ Examination performed at School of Tropical Medicine, San Juan.

Rico Department of Health and 1 case by the School of Tropical Medicine (6).

Although details regarding types of affected animals are not available for all the years, the only species mentioned in the literature are dogs and various types of farm animals. Until the present outbreak, Puerto Rico had been considered as one of the world's rabies-free areas, no case of rabies having been reported on the island since 1933.

The Present Outbreak

The first known case of the present outbreak was diagnosed in a dog March 22, 1950, on a small farm in Barrio Monacillo of the municipality of Rio Piedras. The animal had shown typical clinical symptoms and had bitten several persons and animals on the farm. A hog, bitten by this first rabid dog, subsequently died of rabies. All persons bitten received the complete series of Semple antirabic vaccinations. The next 3 months marked the occurrence of seven cases: four dogs, one hog, one calf, and one cat. The bizarre geographic distribution involved five widely scattered foci of infection including two barrios in Rio Piedras and one each in Ciales, Toa Alta, and Ponce. The diagnosis of these initial cases was confirmed by the Communicable Disease Center laboratory at Montgomery, Ala., and the School of Tropical Medicine, San Juan, P. R.

Thorough investigation revealed that all of the cases were rural and in no instance was there evidence that the involved foci had as a source of infection any one animal contact which was common to all. Nor was there any evidence to support the hypothesis that any one or several of the cases had stemmed from a recent importation of infected pet animals. The striking fact about the investigation was that all of the originally infected dogs and the cat in the five foci had fought with mongooses within a period varying from 2 weeks to 2 months before clinical illness. This was the first epidemiological suggestion that rabies might be present in the mongoose population and that it possibly was being transmitted from the mongoose to domestic animals.

Several mongooses were trapped and exposed to experimental infection in order to determine

¹ Cats, cattle, horses, goats, swine.

their relative susceptibility and to study the clinical pattern of rabies in these animals. Infected brain suspensions were inoculated intramuscularly (total dose of 0.4 cc., 10-percent suspension, intramasseter) with several of the Puerto Rican strains of virus obtained from the original cases. Two of four inoculated mongooses became infected after incubation periods of 22 and 23 days, respectively. They exhibited progressively typical, if exaggerated, symptoms of furious rabies which lasted 4 and 6 days, respectively, until death.

Like most other wild animals, the normal mongoose has a natural fear of man and many other animals. When it is cornered or caged, however, it becomes extremely vicious. At the height of clinical rabies, it exhibits extraordinary symptoms of hyperexcitability and ferocity. Both of the infected animals suffered broken teeth, lacerated muzzles, and severe oral trauma from biting at the wire and frame walls of their cages. The terminal paralysis which ensued was swift and overwhelming. Negri bodies were demonstrated upon direct microscopic examination, and virus was isolated from the brains and salivary glands of both animals.

Pilot trapping operations were then set up in and around the reported infected areas. The first two naturally infected mongooses were found October 18 and 20, 1950, at Fort Buchanan in the municipality of Bayamon. These had been captured after unprovoked attacks on personnel and animals on the military reservation.

Stimulated by a campaign of public information, increasing reports of clinically rabid mongooses that exhibited signs of unusual bravado

and ferocity began to come into the health department. Corresponding increases in the number of mongoose brains submitted to the laboratory followed. From the onset of the outbreak March 22, 1950, to September 18, 1951, a total of 78 cases of rabies was confirmed by laboratory examination. These included 37 cases in mongooses, 18 cases in dogs, and 23 cases in cats and livestock (table 2). All of the cases were restricted to rural areas and were distributed throughout the island with no significant geographic pattern. Since the beginning of the outbreak, 104 treatments of Semple human antirabic vaccinations have been administered by the health department. The chain of events with regard to the occurrence and spread of the infection established it as primarily an epizootic of rabies in the mongoose population with secondary transmission to dogs and other domestic animals. There is no evidence that the disease has, as yet, become entrenched in the canine population with urban involvement and significant dog-to-dog transmission. Most of the livestock cases which were investigated were caused by exposure from rabid mongooses.

Immediately after the outbreak, emergency control measures were put into effect to prevent the spread of the disease in the large and susceptible dog population. These programs included a thorough census of all dogs, the collection, impoundment, and humane destruction of all ownerless and stray dogs, and the vaccination of all other dogs in the original zones of infection which included an area covering a radius of 3 to 5 kilometers from the focal case. Since Rio Piedras and San Juan were not far

from this area, a similar campaign was carried out in these cities.

As the reports of cases began to come in from other parts of the island, the same intensified control, with emphasis on dog vaccination, was extended to all affected areas. Although mongoose and livestock cases continued to occur in some of the previously infected areas, in no instances were there any cases in dogs in areas where a canine rabies-control program had been conducted. Further evidence of the effectiveness of measures to prevent the disease from becoming established in the dog population is demonstrated by the fact that from January 29 to July 5, 1951, there were no cases reported in dogs, while there were 17 cases in mongooses, 3 in cattle, 4 in horses, and 2 in goats.

Plans were drawn to control the disease in the mongooses of the island by a mongoose trapping program. Two types of traps were put into use, one made of wood and hardware cloth and the other, of simpler design, entirely of wood. Both types employ the principle of placing an attractive bait on a device inside the trap which, when disturbed, springs a trap door shut. Approximately 3,000 traps have been constructed as models and distributed to centers throughout the island. An island-wide program now in operation consists primarily of the training and education of the public for the trapping of mongooses in rural areas of the island. Training centers have been established and training carried out by local health units, 4-H clubs, and agricultural extension services.

Characteristics and Habitat

The mongoose is not native to Puerto Rico or to the other islands of the Caribbean. It was imported from India to Jamaica during the middle of the nineteenth century by sugar planters to destroy the rats which were causing large economic losses in the cane fields. Jamaica apparently served as a distributing point for far-flung exportation. They were introduced into Puerto Rico between 1870 and 1877 (7) and into Hawaii about 1883 (8).

The mongoose has been of little or no value as a biological means of rat control, Spencer

points out in his studies in the Territory of Hawaii. In comparing the rat populations of the principal islands on which the mongooses were introduced with those of the islands of Lanai and Kauai where they were not released, he shows that the over-all rat population densities remained the same. This species of mongoose is diurnal in habit while the rat is nocturnal. Their paths rarely cross. Furthermore, Spencer says, the mongoose is as much of a scavenger as a predator, has no aversion to feeding on carrion, and will try to obtain his food in the easiest way possible (9).

The experience in the West Indies has been much the same, and over the years it was found that the mongoose, rather than being an asset, has been a liability. It has greatly reduced, and even exterminated, most species of ground-nesting birds by preying on eggs, nestling birds, and adults. It has also reduced great numbers of beneficial insectivorous lizards and toads and has been a serious pest of poultry by decimating young chicks and eggs. As a result, most of the islands have, from time to time, attempted to initiate mongoose reduction programs, usually by some kind of bounty scheme, with varying degrees of success (10). Now that the animal has been proved an important disease vector, interest in devising effective reduction programs has been revived.

Although this species abounds in India, it has not been listed as an important vector of rabies in that country, where the jackal is the principal wild host and transmitter of the disease (12). However, in South Africa, other species of the family Viverridae are described as important vectors of rabies. These veld carnivora include the yellow mongoose, *Cynicits penicillata*; the suricate, *Suricata suricatta*; the small gray mongoose, *Myonax pulverulentus*; and the genet cat, *Geneta felina*. The first two are burrowing animals while the latter two are not (13-15). The South African types of mongooses often are referred to as meercats.

Summary

1. Puerto Rico is experiencing an outbreak of rabies which began with the first reported case March 22, 1950.
2. This was the first case of rabies reported

since October 15, 1933, with only sporadic cases having been diagnosed in the years before that time.

3. A thorough study of the outbreak has established it as primarily an epizootic of rabies in the mongoose population of the island with secondary transmission to dogs and other animals.

4. This is the first major outbreak of rabies in the Western Hemisphere attributed to the Indian mongoose, *Herpestes javanicus*.

ACKNOWLEDGMENTS

The authors express their appreciation to Health Commissioner Juan A. Pons for making this study possible; to Martha Eldson, Dr. Enrique Koppisch, Manuel Betances, and Antonio Puras for their assistance in the diagnostic phases of this work; to Dr. Enrique Toro, Jr., Dr. Aurelio Malaga Alba, and William Buren for their active participation in the control activities; to George A. Seaman, Nelson Biaggi, Luis Hernandez Aquino, José Ramos, and Dr. Virgilio Biaggi for supplying important sources of historical and scientific information.

Heart Center for Children

Plans for a new center to serve children with congenital heart malformations have been approved by the Children's Bureau, Federal Security Agency. This center, the second regional heart program of its kind, will be located in California and will serve children in that State, Arizona, Idaho, Nevada, Alaska, and Hawaii.

According to arrangements completed with the California State Department of Public Health, the center will use four hospitals, three in San Francisco, the Mt. Zion, Stanford, and University of California, and the Children's Hospital in Los Angeles.

The first heart center, approved last August, is in Connecticut and serves children from Connecticut and Rhode Island. Studies are now being made to determine the best locations for centers in the South, East, Midwest, and Southwest.

Expenditures of Health Departments In Large Cities

By ISADORE SEEMAN, M.P.H.

Adequate financial support for public health services is essential if the benefits of modern public health practices are to reach the people. Although it has often been said that public health is purchasable, there has been insufficient attention to the problem of setting the price. If appropriating bodies are expected to provide adequate funds, we should be prepared to offer sound objective standards against which the funds requested may be measured.

Health officers annually submit budget requests which include sums for many new positions. Budget officers annually reduce these requests, usually allowing necessary increments in salaries and here and there permitting the creation of additional jobs. All of us are familiar with the arithmetic of the budget office: the sum of the requests from all of the government departments exceeds anticipated revenue; therefore, unless new sources of income are sought there can be no other recourse than to cut the departmental requests. If health department officials hope to do more than bargain for an arbitrary share of the total appropriation for governmental services, efforts must be made to develop a more rational and more precise approach to budget preparation and justification.

In recognition of the need for organized effort to insure adequate public funds for health

services, the health council of the District of Columbia has adopted as one of its functions a program of study and action to develop community understanding and support for the budget needs of the official health department. A committee of lay persons, organized for this purpose, directed the author to prepare data to assist in such a study, with particular reference to comparisons of expenditures in other communities of comparable population size. This paper presents the data collected as a part of this study, together with a discussion of some of the problems in developing effective justifications for public health appropriations.

This study is limited to public health expenditures in large cities. For 33 of the largest cities in the United States, data collected by the U. S. Census Bureau for 1948 (1) show a median expenditure for public health services of \$1.18 per capita. Detailed data on expenditures, by service and by source of funds, were collected by the author from 11 large cities which could furnish such figures. The aggregate population of these 11 cities was approximately 8 percent of the total United States population. In 1948, the median health department expenditure of these 11 cities was \$1.54 per capita. These expenditures cover only the traditional activities of a health department and do not include programs of hospital or medical care. There was a considerable range in total expenditure among these 11 cities, with a low of 98 cents per capita and a high of \$2.40 (table 1).

Factors Influencing Health Expenditures

What factors determine the amount of funds appropriated to the health department in any community? Obviously many complex factors may play a part. Some of the measurable factors which might possibly have a relationship to total municipal expenditures for health services were studied for 10 cities. (Buffalo was excluded from this analysis because comparable data were not available.)

There appears to be a definite relationship between the per capita amount spent for health

and total municipal revenue from taxes (table 2). When the cities were ranked according to health expenditure and grouped as the highest or lowest three and middle four, 7 of the 10 cities fell into identical groups when health expenditure was compared with tax revenue. This relationship is illustrated by comparing the figures for 1948 for Baltimore, which had a per capita health expenditure of \$1.53 and a per capita tax revenue of \$55.82, with those for Pittsburgh, where the health expenditure was \$1.04 and tax revenue was \$36.85 per capita (table 2). Health expenditures were also related to per capita total municipal operating expenditures for all purposes. Six cities fell into identical groups according to these two factors. This suggests a conclusion which, while rather obvious, is nevertheless important: a city may be expected to appropriate funds for health services in relation to total funds secured from its basic revenue source and to total funds available for all operating services. This principle is further supported by the fact that health expenditures do not rank highest in those cities where borrowing is greatest.

How much should a community spend for its public health program? The committee on local health units of the American Public Health Association considered that approximately \$1 per capita, based on the 1942 purchasing power of the dollar, would be required "to assure basic and reasonably adequate local health services" and that \$2 or \$2.50 per capita might be needed "to provide also such addi-

tional services as may be found to be locally desirable and considered to be essential for an optimum local health service of comprehensive scope and superior quality" (2). Emerson found that for the Nation as a whole in 1942 actual expenditures for local health services were only 65 cents per capita. Recognition was given at that time to the need to adjust the recommended figures as the dollar value changed, and in a discussion in the 1947 American Public Health Association meeting (3), it was suggested that the \$1 minimum per capita be raised to \$1.50 in view of the increased cost of providing the same basic services. On this basis a more adequate budget would require \$3 or \$3.75 per capita.

An analysis of the relationship between an index of purchasing power and per capita health expenditure in the 11 cities studied reveals that those cities with a higher cost of living tend to spend more per capita for health. However, adjustment of the actual health department expenditure in these cities for differences in the cost of living suggests the inadequacy of appropriations for health services (table 3). If the minimum per capita need of \$1.50 is used for the city with the lowest cost

of living index, the city with the highest living cost would require not \$1.50 but \$1.71 per capita to provide the same services, assuming the cost of health service bears a relationship to the cost of living. When actual expenditures are adjusted for the cost of living factor, only four of the 11 cities exceed their minimum need.

The observations on the relationship between health expenditure and total municipal operating cost suggest another possible approach to the establishment of a standard for a community's health expenditure. Should a city be asked to devote some recommended minimum percentage of its total expenditure to health services? For the 10 cities studied, the actual percentage in 1948 ranged from 1.3 to 4.2, with a median of 2.8 percent (table 2). It should be noted, however, that for these cities there is no significant relationship between the level of per capita health expenditures and the percentage of total city expenditures devoted to health. Boston, for example, allocated the smallest percentage of total expenditure to health, but ranked second among the 10 cities in per capita health expenditure.

We are forced to recognize the problem of city fiscal officers faced with requests for more funds than are available. The health department might seek an "equitable" share of the available funds. If such an allocation is still inadequate based on other criteria, the alternatives are to increase health appropriations at the expense of other municipal services, or to increase municipal revenue.

There is a striking relationship between a health department's expenditures in 1 year and the record of expenditures by the same health department in past years. This relationship is clear even when the expenditure in 1948 is compared with the expenditure in 1920. When the 11 cities are ranked, major shifts in relative positions are seen to have occurred over this 28-year period in only 4 cities (table 1). Two of the four cities whose rank shifted significantly also experienced radical population increases during the period, both over 90 percent. One city maintained the same rank in both 1948 and 1920, four cities shifted only one position in rank, and two cities shifted two positions. In short, a community spends for health services at the rate it is accustomed to maintain.

³ Expenditures for 1949.

Source of Local Health Department Funds

There is no significant relationship between per capita health department expenditures and the size of the city's population. This is true for the 11 cities studied as well as generally for larger and smaller cities. For the five largest cities in the United States which have populations over 1,000,000, the median per capita health expenditure in 1948 was \$1.15; for eight cities between 500,000 and 1,000,000 population, it was \$1.58; and for 20 cities between 250,000 and 500,000 population, the median expenditure was \$1.11 per capita.

Of the major municipal functions, only libraries and penal institutions receive a lower per capita allocation than public health service. For 10 large cities, the 1948 Census Bureau tabulation shows a median health expenditure of \$1.40 per capita. This compares with a per capita expenditure of \$2.39 for public welfare, \$2.87 for public recreation, \$3.20 for highways, \$3.76 for public hospital care, \$5.73 for municipal sanitation (including garbage collection and disposal, street cleaning, and sewage disposal, but not including the public health sanitation services of food and milk control, environmental hygiene, and related activities), and \$13.15 for public safety. The median expend-

iture for penal institutions was 78 cents and for public libraries was \$1.16 per capita.

Seven of the 11 cities studied were included in the 1948 tabulation of total community health and welfare expenditures by community chests and councils of America (4). For these seven cities, the median per capita expenditure from public funds for all health and

¹ Funds from State sources were reported only for Baltimore (0.3 percent).

² Expenditures for 1949.

hospital services was \$9.48. The median health department expenditure in these seven cities was \$1.64 per capita. It is thus apparent that the expenditure by the health department for traditional public health activities in these cities represents only a relatively small part of the public dollar spent for health care.

Source of City Health Department Funds

The large city health departments studied relied almost exclusively for their funds on local appropriations. In nine cities for which data were available a median of 92.4 percent of health department expenditures was derived from the city and county. State funds made available to the large city health departments reported on were negligible. This may not, in all cases, reflect services provided in the city by the State health department directly under State appropriation, but, in general, such services are very limited in metropolitan communities. Large cities do not depend on Federal funds for any significant proportion of their expenditure. The percentage of city health department expenditures derived from Federal grants ranged from 2.6 to 18.7, with a median of 7.6 percent (table 4). The highest percentage, 18.7, is for the District of Columbia, which, for its Federal grants, is treated as a State.

Expenditures by Service

It would be helpful to have available bases for justifying adequate appropriations for specific services. Suggestions have been made for minimum ratios of personnel to population in a number of public health fields (2). Another and more precise approach has been to develop personnel needs in man-hours, estimating the time required for each type of service and the units of service to be rendered. In illustration of this technique, the total number of environmental sanitation inspections required in the District of Columbia was estimated for 1952 at 190,795 visits. The record shows an average of 2,500 inspections per worker per year. Thus a need for 76 inspectors can be demonstrated. It might be helpful if one could point to morbidity or mortality records as evidence of the need for adequate appropriations. Unfortu-

nately the use of such justifications is accompanied by hazards. Where the death rate is high, the need for efforts to effect a reduction can be used to justify a large appropriation. On the other hand, where the mortality rate is low, in part as a result of earlier activities, there is a need to maintain control programs in order to avoid a relapse. Further, the reduction of a low mortality rate requires relatively greater effort than the reduction of a high rate. Thus, large appropriations can be justified by either a high or low mortality rate.

In the 11 cities studied, medical and nursing services accounted for a median of 61 percent of the total health department expenditures in 1948 (table 5). About half of this amount, 29 percent, was spent for nursing services. Sanitation programs accounted for 26 percent of all expenditures; laboratory services for 5 percent; and administration, vital statistics, and health education, for 10 percent.

Within the field of medical programs, the median percentages devoted to specific services were: tuberculosis, 6 percent; venereal disease, 6 percent; maternal and child health, 5 percent; school health, 4 percent; and communicable disease, 3 percent. Other programs, such as cancer

The Health Department Dollar

percent. Whether these differences are accounted for by variations in the scope of program, in the volume of service rendered, or in the unit cost of providing the service could not be ascertained. Studies to determine the reasons for such wide variations should prove enlightening.

The Trend of Expenditures

A study of municipal health department expenditures was undertaken by the American Public Health Association in 1921 covering 83 cities with populations over 100,000 (5, 6). In 1923 the United States Public Health Service surveyed the 100 largest cities (7). Later, data on expenditures of health departments were available from reports on the Health Conservation Contests (8, 9). From these studies some trends can be observed. Average per capita expenditures of the health departments studied increased over 200 percent between 1920 and 1948, rising from \$0.48 to \$1.54 (table 5). The total medical-nursing cost increased from 22 to 79 cents per capita, the nursing cost alone from

1 to 44 cents. Expenditures for communicable disease were 8 and 7 cents per capita in the 2 years. Tuberculosis cost increased from 2 to 10 cents; venereal disease, from 1 to 8 cents. Sanitation expenditures increased from 16 to 39 cents per capita. The cost of administration increased from 3 to 10 cents per capita.

The medical-nursing programs are the most expensive in the public health field and have shown sharp rises in cost. The newer programs being undertaken by public health agencies, such as cancer and other chronic disease control, fall within this field. The implications for financing these added services cannot be ignored.

Significant shifts in program emphasis can be observed from an analysis of changes in the percentage distribution of health department expenditures by field of service. The total medical-nursing program cost increased from 46 to 61 percent of the health department budget. Nursing services are, of course, an aspect of the service programs in communicable disease control, maternal and child health, and other medical activities. Nevertheless, in many

only. Typhus fever was reportable in nine States; typhoid fever, in seven. This latter disease was reportable also in a few cities. Measles and whooping cough were reportable in only a very few cities and in no States. Tuberculosis was reportable in two States in 1901. Syphilis and other venereal diseases were not reported at all. Pneumonia was reportable only in Hartford, Conn.; malaria, in Oakland, Calif.; and hydrophobia, in Ohio only. Thus our present administrative procedures and complicated reporting systems have developed during this past 50 years.

Original Purpose of Required Reporting

The primary purpose was to determine, as early as possible, the presence in the community of "diseases dangerous to the public health." This was done in order to institute, as rapidly as possible, isolation procedures for the individual and quarantine of the family household, the infected arriving ship, or even the quarantine of a whole community.

As early as 1743, a Charleston regulation required reporting by the incoming ship's captain to the pilot of the port of any illness aboard. At first the infected vessels were quarantined in the roadstead until everyone died or recovered. A few years later, Charleston was the first American community to establish a pesthouse on land.

Quite logically, during most of the nineteenth century, no reporting was required of tuberculosis, pneumonia, infantile diarrhea, malaria, typhoid fever, nor any other of the common infections, since these were believed to be due to environmental factors such as poisoned air, decaying vegetables or animals, bad smells, or perhaps telluric influence. Thus, isolation and quarantine were thought to be of no value in checking these diseases. At this time, as we have noted, the only diseases to be reported were smallpox, yellow fever, and cholera. They were reported because they were epidemic, virulent, and obviously contagious diseases that were dangerous to the public health, and against which active protective measures might be taken.

This broad general urgency to check pestilence is still our primary motive in requiring the reporting of communicable disease.

New Concepts in Disease Reporting

As the science of epidemiology developed and more and more information was obtained about the general principles of the etiology and mode of spread of contagion, we began to desire more accurate and detailed epidemiological information concerning all communicable diseases. Thus, there grew up rapidly a long list of diseases which the health department insisted must be reported. Physicians resented this intrusion on their time, and objected strenuously to revealing personal (often confidential) matters relating to their private patients. This resentment has continued through the years, particularly when the physician could not see that anything would be gained—either of direct benefit to the community or to his patient—from these reports. It is common knowledge that many private patients insisted that their physicians should not report their diseases to the authorities. This was particularly true in the case of tuberculosis and venereal disease, as well as other conditions that bore a social stigma.

Thus, although the States and local health departments built up elaborate plans for the reporting of an all-inclusive list of communicable diseases, only a relatively few of these diseases have ever been reported adequately (by "adequately" I mean 90-percent completeness). There is now good reason to believe that the disinclination of physicians to report certain communicable diseases will increase rather than decrease. They see no particular need for reporting gonorrhea at the present time, since the patient will be cured before the report reaches the office of the health department. Why report lobar pneumonia, queries the physician, when the health department has no measures of prevention, no specific diagnostic tests are required, and therapy is so effective?

It is clear that the physicians of the next decade will pay little attention to the regulations relating to reporting. Most doctors will report promptly a case of communicable disease that may require hospitalization, a diagnostic facility, or a follow-up service. But when notification of a disease is regarded as a simple formality, without apparent direct benefit to the patient, to his family, or to the community,

the procedure of reporting will often be neglected.

If we are realistic, we know that the physician looks at epidemiologists with a quizzical eye and asks a very pertinent question:

"What is your purpose in requiring me to notify you of the existence of a case of communicable disease? What is to be gained thereby? The changes in the natural history of disease, coupled with social and medical growth, have made these procedures unnecessary. The improvement in community and personal hygiene, the development of new methods of control, the advancement in procedures for more accurate and more rapid diagnosis, and the almost explosive increase of specific therapy have made obsolete this practice of reporting communicable disease to the health department."

Your answer may be that the purpose of notification is to enable the health officer to institute measures that will prevent further spread of serious infection. Thus, the primary object is the rapid and complete reporting of diseases of high infectivity and a high degree of fatality.

In the past, this was a perfectly reasonable demand. Yellow fever, typhoid fever, smallpox, cholera, diphtheria, and scarlet fever all fell in this general category and all were well reported. In each of these diseases, definite control measures became available which were effective and most satisfactory, both from the point of view of the patient and the community.

But the practitioner, who is the source of almost all our information in early discovery of communicable diseases, will promptly point out that the diseases which we have mentioned, including malaria and most of the rickettsial diseases as well, no longer appear in our mortality tables. Actually, they are well under control.

Recently, the Chief Medical Officer of Scotland (3)¹ emphasized that, at the present time, the major communicable diseases that are dangerous to the public health are such epidemic conditions as food poisoning, influenza, poliomyelitis, infantile diarrhea, etc. He notes that, in these conditions, notification will not prevent

further spread, since known defensive measures have proved of little avail, and our major recourse, therefore, is the prevention of the original occurrence of the disease.

What then is our purpose in requiring the reporting of communicable disease? Are these procedures obsolete?

Essential for Epidemiological Knowledge

Despite this reasonable objection of physicians, we adhere firmly to the philosophy that there is a very sound fundamental reason for required reporting of communicable disease. We realize that this procedure is no longer of great benefit to the sick individual, nor perhaps to his family. But we do believe that the plan is of great community benefit.

Figure 1. Crude death rate per 1,000 population for New Orleans, 1820-1900.

The graph of the death rate of New Orleans 1820-1900 (fig. 1) illustrates the point that yellow fever, smallpox, and cholera were considered the pestilential and, thus, the reportable diseases of the last century.

The peaks of the graph were produced by these three diseases. But the great mass of unnecessary deaths (see shaded areas) were due to "natural causes" and were taken as a matter of course, and as a part of normal expectancy in life. The major causes producing these deaths were diarrheal diseases of infants, tuberculosis, communicable diseases of childhood, and water-borne infections. None of these dis-

¹The author is indebted to this article for many of the ideas presented in this paper.

eases were reportable until comparatively recent years, beginning about 1900.

Philadelphia has had a better health record than almost any of our large cities. But in 1794 it had the greatest disaster, in proportion

Figure 2. Crude death rate per 1,000 population for Philadelphia, 1810-90.

to the population, that any American city ever suffered. This was the yellow fever epidemic which caused over 4,000 deaths in some 35,000 population. As figure 2 shows, cholera and smallpox were considered the greatest menaces

to Philadelphia. But in 1868-72 the tuberculosis death rate was 320.7 per 100,000 population, and the death rate from diarrhea and enteritis was 235.4. Neither of these conditions was reportable because neither was considered pestilential.

The great peaks in the mortality curves disappeared in all areas in the Nation about 1900. The only exception during the past 50 years has been the relatively small peak caused by the influenza epidemic in 1918.

A completely different reason for reporting communicable disease was developed during the twentieth century, beginning about 1900. The major purpose was to elucidate the natural history of the disease "in distinct epochs of time at varying points on the earth's surface" (Frost's definition). The accumulation of these invaluable data for poliomyelitis is illustrated by figures 3, 4, and 5. These data are not mortality, but morbidity data; not deaths from a disease, but its prevalence. They can be obtained only by accurate and complete reporting. These graphs bring out the point that the primary purpose of disease reporting at the present time is to enable the epidemiologist to study the natural history of disease. Some of the results

Figure 3. Poliomyelitis cases reported in the United States, 1915-46.

Figure 4. Weekly incidence of poliomyelitis in the United States, 1941-45.

that will be obtained by careful communicable disease reporting may be cited:

1. An analysis of the trends of the prevalence of the disease.
2. Its distribution in various age groups, its sex preference, and its appearance in social groups and in groups of varying economic status.
3. The geographic distribution of the disease and its geographic variations through the years.
4. The seasonal distribution of the disease under study and its correlation with other readily measurable environmental factors.
5. Changes in case fatality ratio.
6. Changes in actual virulence of the infection.
7. The benefits of new methods of therapy in reducing: (a) severity of the illness; (b) period of hospitalization; (c) risk of secondary attacks; and (d) incidence of carriers.

These and many more are the epidemiological reasons that give us complete justification for

Figure 5. Percentage distribution of poliomyelitis cases by age in Chicago and Detroit, 1939-44.

the regulations requiring reporting of communicable disease. In summary, let us return once more to Frost's definition of epidemiology: "It is the science which considers the distribution, occurrence, and types of diseases of mankind in distinct epochs of time at varying points on the earth's surface, and will provide an account of the relations of these diseases to in-

herent characteristics of the individual and to the external conditions surrounding him and determining his manner of life."

Conclusion

Only through a satisfactory, accurate, prompt system of disease reporting can the science of epidemiology be implemented. It is the cornerstone of the whole structure of the science.

Sale of Dangerous Drugs Restricted by New Law

Drugs which may be dispensed only upon a physician's prescription are now clearly defined by a Federal law, the Durham-Humphrey amendment to the Federal Food, Drug, and Cosmetic Act, which will become effective April 26, 1952. After that date drug manufacturers will be required to label all such drugs with the legend: "Caution: Federal law prohibits dispensing without prescription." Thus, retail pharmacists will be able to tell immediately from the package whether or not a drug is one which requires a prescription.

The new law restricts to prescription sale any drug which "because of its toxicity or other potentiality for harmful effect, or the method of its use, or the collateral measures necessary to its use, is not safe for use except under the supervision of a practitioner licensed by law to administer such drug." The Food and Drug Administration interprets this definition to include, as unsafe, drugs for serious diseases which cannot be treated effectively by the layman. An example of such a drug would be penicillin, which is nontoxic but which requires expert medical knowledge for effective use in treating certain diseases, such as pneumonia.

Under the new bill, prescriptions for drugs which bear the "Caution" label may not be refilled without specific authorization of the prescribing physician. However, drugs which do not require a prescription for the first sale may be sold across the counter in the original package, or as a refill of a prescription without further authorization by the physician.

The new law legalizes telephoned prescriptions for all drugs. Such prescriptions for restricted drugs, however, must be put promptly in writing and filed by the pharmacist.

This legislation will strengthen control over the sale of such drugs as barbiturates, amphetamines, sulfa drugs and antibiotics, thyroid, and male and female sex hormones.

The ethics of the pharmaceutical profession have always required that dangerous drugs be dispensed and prescriptions for them be refilled only on instructions from the physician. The new law makes it legally mandatory for all druggists to follow these practices.

Units of Radiation and Radioactivity

By ELDA E. ANDERSON, Ph.D.

Measurements, and the units in which the measurements are to be made, are important in any discussion of a scientific subject. We begin to know something about a physical quantity when we can measure it. If we are to assess the hazards associated with radioactivity, if we are to use the radiations for therapy, for biological research, and in industry, we must be able to measure the strength of our radioactive source, we must be able to measure the radiation dose received; and to do so, we must have units in which to make the measurements.

As in any growing and expanding science in which our knowledge is still limited, agreement on measurements made in different laboratories is not perfect, and as yet agreement on terminology and in the magnitudes of all units has not been reached. Some confusion results, but we can reduce such confusion by a knowledge of, and exactness in, the terms used.

Curie

Let us turn first to units for measuring the activity of a radioactive source. Determination

Dr. Anderson, chief of education and training in the Health Physics Division of the Oak Ridge National Laboratory, Oak Ridge, Tenn., presented this paper at the inservice training course in Radiological Health at the School of Public Health, University of Michigan, Ann Arbor, in February 1951. It is reproduced by permission from the published lectures as background material for Dr. Straub's report on Radioactive Materials and Their Effects on Environmental Health, page 298.

of the absolute activity of radioactive samples is highly important in dose determinations and is based on the number of atoms disintegrating per second. Conventionally, the unit of activity or quantity of radioactive material is the curie. When the principal radioactive element in general use was radium, there were two well-defined units for expressing the quantity of radioactive material. One was simply a gram of radium, which could be determined by weighing. Amounts of radium were then determined by comparing the gamma radiation of the unknown sample with that of a carefully weighed standard, when conditions of filtration, instrument for measuring the radiation, and geometry all were the same.

Since in many cases radon is used in place of radium, a second unit named the curie was defined as that quantity of radon (0.66 mm.³ at 0° and 760 mm. Hg) in radioactive equilibrium with 1 gram of radium. In 1930, the curie was extended to include the equilibrium quantity of any decay product of radium—that quantity of a decay product of radium which has the same disintegration rate as a gram of radium, or that has the same number of atoms disintegrating per unit time as 1 gram of radium. Measurements of the absolute decay rate of radium are not in perfect agreement; hence, the number is not precisely known, and in 1930 the International Radium Standard Commission recommended using the value of 3.7×10^{10} disintegrations per second. (A millicurie corresponds to 3.7×10^7 dis/sec.; 1 microcurie, to 3.7×10^4 dis/sec.)

The curie has become widely adopted as a measure of the quantity of any radioisotope and not limited to members of the radium family as recommended by the commission. Thus, 1 mil-

licurie of P^{32} , Na^{24} , or C^{14} means the amount of the isotope necessary to provide disintegrations at the rate of 3.7×10^7 atoms per second. Failure to distinguish between total ionizing events and total disintegrations in the case of isotopes that do not have simple decay schemes has led to confusion and error in the use of the curie. For example, with a radioisotope that emits both a beta ray and a gamma ray in each disintegration, if there are internal conversion electrons, measurement of the beta particles will lead to a too-high disintegration rate. If only the gammas are measured, a too-low disintegration rate results. Unless the number of gammas leading to conversion electrons is known, the disintegration rate will not be correct and the amount of the radioactive isotopes expressed in curies will be incorrect.

Likewise, consider the error which could arise in measuring the activity of Mn^{52} which has a half-life of 6.5 days and decays by positron emission in 35 percent of the transitions and by electron capture in 65 percent of the transitions. One millicurie of Mn^{52} emits only $0.35 \times 3.7 \times 10^7$ or 1.3×10^7 positrons per second, even though there are 3.7×10^7 disintegrations per second.

The use of the curie to describe any radioactive source which produces the same gamma ray response as 1 curie of radon is another serious misuse of the curie unit. The objection is that the gamma ray response depends on the detection instrument used. For example, the ratio of the apparent gamma ray intensity of a source of 8-day I^{131} to a source of radon is four times as great if measured with a platinum cathode counter as when measured with a copper cathode counter. The curie should be used strictly to mean that quantity of radioactive material which has 3.7×10^{10} atoms disintegrating per second.

Rutherford

Since there is a discrepancy between the number of disintegrations per second from 1 gram of radium and the number adopted by international agreement, Curtis and Condon proposed a new unit for radioactivity, the Rutherford, defined as that quantity of a radioisotope decaying at a rate of 10^6 disintegrations per

second. However, this unit has not come into widespread use. The unit used to compare source strengths is the roentgen-per-hour-at-unit-distance, which we shall define after discussing the roentgen.

Dose Units

Roentgen

A unit of radiation dose should be readily reproducible and should be measurable in terms of simple physical quantities by routine instrumentation. In most cases the ultimate information desired is the biological damage produced by a given dose of radiation; hence, it would be desirable to have our unit of radiation dose proportional to the biological damage produced. However, the factors involved in radiation damage are so complex and so little known that it has not been possible to devise a unit having both these physical and biological characteristics. The physical quantity selected must be capable of being measured with reasonable accuracy and of being expressed in absolute units. Thus, the unit of dose may be either the energy absorbed from the radiation per unit mass or the ionization produced per unit of mass.

If we select as our physical quantity the energy absorbed per unit mass of tissue, we may measure the energy in ergs or multiples of ergs, i. e., joules (1 joule is 10,000,000 ergs). In recent years another energy unit has come into widespread use because of its convenience, the electron volt, which is defined as the energy an electron acquires in falling through a potential difference of 1 volt. Frequently used is the unit Mev, which is 1 million electron volts, or that energy which an electron would acquire in falling through a potential difference of 10^6 volts. Today, particles with energies of many Mev are commonplace. Since both ergs and electron volts measure the same quantity, they must be numerically related, and therefore, we find that 1.6×10^{-12} ergs is equivalent to 1 electron volt (e. v.) or 6.2×10^{11} e. v. = 1 erg.

If our unit of dose is the ionization per unit mass produced by the radiation, we would measure it in terms of the number of charges formed per unit mass. The unit of charge we shall use is the electrostatic unit. Whichever unit of

dose is employed, energy absorbed per unit mass or ionization per unit mass, the ionization produced per unit volume is the physical quantity actually measured.

The roentgen is that "quantity of X- or gamma-radiation such that the associated corpuscular emission per 0.001293 gram of air produces, in air, ions carrying 1 esu [electrostatic unit] of quantity of electricity of either sign (2)." The quantity of air referred to is 1 cc. of dry air at 0° C. and 760 mm. Hg. The roentgen (r.) is a unit of radiation exposure and is based on the effect of X or gamma radiation on the air through which it passes and applies only to X or gamma radiation in air. The unit considers the ionization caused by the secondary particles (electrons) ejected from some known volume of air (1 cc. at standard conditions). The ionized tracks of these particles may go outside of the known volume, but it is important that their total ionization be collected wherever it occurs.

The roentgen is not a radiation unit. It does not describe the number of photons in the beam nor their energy; it merely gives the effect of that radiation in 1 cc. of air. Part of the energy of the radiation is given to the air in producing photoelectrons, Compton electrons or in pair production, and these secondary particles in turn produce other electrons and positive ions. When all ions of either sign are counted and are found to be 1 esu, then 1 roentgen of X or gamma radiation has been absorbed by the original volume of air. Since the charge on 1 electron is 4.8×10^{-10} esu (electrostatic units),

the 1 esu of charge represents $\frac{1}{4.8 \times 10^{-10}}$ or 2.083×10^9 electrons. This is also the number of ion pairs per esu, since only one partner of the ion pair is measured. Thus, the roentgen may be defined as that quantity of X or gamma radiation such that the associated corpuscular emission per 0.001293 gram of air produces, in air, 2.083×10^9 ion pairs, or 1.61×10^{12} ion pairs per gm. of air. Since the energy required to form an ion pair in air is 32.5 e. v., the roentgen represents energy absorption of 6.77×10^4 Mev/cc. of air, or 5.24×10^7 Mev per gm. of air, or 5.24×10^{13} e. v. $\times 1.60 \times 10^{-12}$ ergs/e. v. = 83.8 ergs/gm. of air.

Thus 1 roentgen of X or gamma rays is that

quantity of radiation in which approximately 83.8 ergs are absorbed per gram of air. Thus, according to the official 1937 definition, a dose of 1 roentgen received at any point means:

- 1 esu of ion pairs produced per cc. of air.
- 2.083×10^9 ion pairs produced per cc. of air.
- 1.61×10^{12} ion pairs produced per gm. of air.
- 6.77×10^4 Mev absorbed per cc. of air.
- 5.24×10^7 Mev absorbed per gm. of air.
- 83.8 ergs absorbed per gm. of air.

One roentgen of X or gamma rays is that quantity of radiation whereby 83.8 ergs are absorbed per gram of air, but in substances of different atomic number and different density the amount of energy absorbed per unit volume for the same quantity of radiation will be different. In soft tissue the energy absorbed per gram of tissue per roentgen is approximately 93 ergs, while in bone it may be higher. Although the relative amounts of energy absorbed in different substances show wide variation, the dose is still 1 roentgen if the same quantity of radiation produces 1 esu of charge of either sign per 0.001293 gram of air at the point under consideration. The dose expressed in roentgens is totally independent of the absorbing medium exposed to the radiation and of the amount of energy that the particular medium absorbs. Nor does the roentgen depend on the time required for the production of the ionization; as long as 1 esu of charge of either sign is produced in 1 cc. of standard air, the dose delivered is 1 roentgen regardless of whether it took 1 second or 1 hour to produce the 1 esu. Consequently, dosage rates are given in roentgens per hour. For example, if a constant dosage rate of 2 roentgens per hour is continued for 5 hours, the total dose delivered is 10 roentgens, and in the 1 cc. of standard air 10 esu of charge is produced.

Since the definition of the roentgen requires that the total ionization produced by the secondary electrons formed per cubic centimeter of standard air be measured, and as some of the secondary electrons may have ranges of several meters, large and cumbersome apparatus would be needed. To avoid such large unwieldy apparatus, "air wall" roentgen chambers or "thimble chambers" have been developed. Their use is based on the principle that, when a tiny cavity such as a small ionization chamber is placed in a large homogeneous absorbing medium which is

uniformly irradiated, the atmosphere of secondary electrons in the cavity is identical in every respect with the electron atmosphere which existed in the medium before the cavity was introduced. If the chamber gas is air, and if the walls are composed of materials having an atomic number near that of air, the ionization per gram of air in the chamber will be substantially the same as the gamma-ray energy loss per gram of air at the point where the chamber is located.

Roentgen-Equivalent-Physical

The roentgen applies only to X-ray and gamma radiation; however, ionization in tissue is often produced by radiations other than photons, that is, by betas, alphas, neutrons, and protons. Thus, there is need for a dose unit applicable to corpuscular radiation, which will be a measure of the energy absorbed in tissue exposed to these radiations. The roentgen-equivalent-physical (rep), introduced by H. M. Parker, is defined as that dose of any ionizing radiation which produces energy absorption of 83 ergs per gram of tissue. Thus, if the energy loss by ionization in the tissue is the same as the energy loss for 1 roentgen of gamma radiation absorbed in air, the dose is referred to as 1 rep. The name implies physical equivalence with the roentgen, but in general such equivalence does not exist, for the rep is not equal to the energy absorbed per gram of tissue exposed to 1 roentgen. The energy absorbed in tissue exposed to gamma radiation depends on atomic composition and density of the tissue as well as on the energy of the photons, whereas a rep is always 83 ergs per gram of tissue independent of kind of tissue or the energy and type of the corpuscular radiation. In soft tissue, a dose of 1 roentgen corresponds to the absorption of approximately 93 ergs per gram. There has been considerable discussion in favor of changing the rep to 93 ergs per gram of tissue, and some persons prefer the use of 95 or 100 ergs per gram.

Roentgen-Equivalent-Man

The biological evidence indicates that the effects of the various ionizing radiations are not the same and that a different degree of tissue damage can be expected from the absorption of

100 ergs of alpha-ray energy than from 100 ergs of beta-ray energy or from 100 ergs of neutron energy. The roentgen-equivalent-man (rem) is that dose of any ionizing radiation which, delivered to man, is biologically equivalent to the dose of 1 roentgen of X or gamma radiation. The rem is not a measure of energy absorption or of ionization produced in tissue, but is rather a measure of a quantity of radiation that produces certain observed biological effects. Extensive experimental studies have been made of the relative biological effectiveness (RBE) of the ionization produced in tissue by the various types of ionizing radiations and an equal amount of tissue ionization due to gamma rays. The values obtained for the various radiations show rather wide variations with effects (blood counts, median lethal dose) and with different species of mammals. Present accepted RBE values are:

Beta rays-----	1
Protons -----	10
Alpha rays-----	20
Fast neutrons-----	10
Thermal neutrons-----	5

In terms of energy, $1 \text{ rem} = \frac{95}{\text{RBE}} \text{ ergs/gm. tissue}$ or, in terms of the rep, $1 \text{ rem} = \frac{\text{rep}}{\text{RBE}}$.
Thus, for alphas, $1 \text{ rem} = \frac{95}{20} \text{ ergs/gm. tissue}$; $1 \text{ rem} = \frac{1}{20} \text{ rep} = 0.05 \text{ rep}$.

The maximum permissible tissue dose for X-rays and gammas is 0.3 rep per week, while for alphas it is 0.015 rep per week, and for fast neutrons, 0.03 rep per week; or, expressed in rem per week, for X and gammas 0.3 rem per week, for alphas 0.3 rem per week, for neutrons 0.3 rem per week. Since a rem of alphas produces the same biological damage as a rem of gammas or a rem of neutrons, doses expressed in rems are additive. Thus, an exposure to 100 millirem (mrem) of gammas and 200 mrem of neutrons is a total dose of 300 mrems.

Roentgen-Per-Hour-at-One Meter

Having defined the roentgen, we can now discuss the unit of radioactive source strength, the roentgen-per-hour-at-unit-distance. For a

particular radioactive substance which emits gamma rays, this unit provides a means of stating the amount of that substance without knowledge of its disintegration scheme. The roentgen-per-hour-at-one-meter (rh_m) is that amount of a radioactive isotope whose unshielded gamma-ray emission produces 1 roentgen per hour in air at a distance 1 meter from the source. By use of a standard instrument reading in roentgens per hour, a standard technique, and the rh_m, the source strength of various gamma-ray emitters can be compared and expressed in terms of the number of roentgens per unit of time, produced at some arbitrary distance. The unit has the advantage in that the disintegration scheme need not be known, whereas it must be known in order to

express quantity of radioactive material in curies.

These then are the units used to express quantities of radioactive materials, the curie and the rh_m; to express dose, the roentgen, the rep, and the rem. With these units it is possible to correlate the effects of radiation on living tissue with external measurements of the exposure, or with calculated internal doses.

Field Training Courses in Insect and Rodent Control

Field training courses in insect and rodent control will be offered during the months of March and April 1952 by the Public Health Service Communicable Disease Center, Atlanta, Ga.

The course in rodent control is scheduled for the period from March 17 to April 4. It is designed to give public health personnel a practical working knowledge of the control of domestic rodents and rodent-borne diseases. Field work, giving the trainee an opportunity to practice the principles developed in classroom lectures and discussions, will be emphasized.

A 2-week course in insect control will be held April 7-18. It will offer practical field training in the control of insects affecting the health and well-being of man. Emphasis will be placed upon the identification, biology, and control of flies, mosquitoes, and household and restaurant insects. Survey and control techniques will be demonstrated, and field practice in Atlanta and surrounding areas will be offered.

These courses are available to interested personnel from State and local health departments and the Public Health Service. Persons from other organizations concerned with insect and rodent control will also be accepted if facilities permit.

Applications should be made by letter through the sponsoring agency to: Officer in Charge, Communicable Disease Center, Public Health Service, 50 Seventh Street, NE., Atlanta 5, Ga. Attention: Chief, Training Branch.

Effect of Radioactive Materials On Environmental Health

By CONRAD P. STRAUB, Ph.D.

In a recent discussion relating to environmental health, Mark D. Hollis (1) indicated that public health officials will be responsible for protecting the population against the harmful effects of ionizing radiation. Ionizing radiations result from the disintegration of unstable nuclei and are damaging to living tissue. The radiation may originate from an external source or from radioactive materials within the body. Radiation from an external source may affect the body as a whole, if there is no shielding, or may be made to affect only certain portions of the body, as in radium treatment of a tumor. Effects of damage from radioactive materials within the body depend on several factors: the quantity of radioactive material present in the body; the type of radiation, whether alpha, beta, or gamma; and the half-life or rate of decay of the material. Other factors to be considered are the organ or organs of localization; rate of excretion from the body, i. e., the biological half-life; the physical state of the individual; etc. All of these factors are considered in determining the maximum permissible concentration (MPC) for each radioisotope

in water or air. The MPC values under consideration for release by the Subcommittee on Internal Dose of the National Committee on Radiation Protection (2) are indicated in table 1.

Inasmuch as the Atomic Energy Commission

Dr. Straub is a sanitary engineer with the Public Health Service Environmental Health Center, on assignment to the Health Physics Division of the Oak Ridge National Laboratory, Oak Ridge, Tenn. This paper was presented at a meeting of the sanitation section of the Georgia Public Health Association in Savannah, May 7, 1951.

supervises the control and discharge of radioactive wastes from its own operations, State and local health officials are not directly concerned with the waste products which result from operations within AEC-controlled areas. Public health officials will be occupied with the discharge of wastes into the environment beyond the controlled area of operations, with the discharge into the sewerage system of radioisotopes from hospitals and research institutions, and with the industrial use of radioisotopes in manufacturing processes, industrial radiography, etc. Industrial hygiene engineers will find considerable opportunity for the exercise of their talents in the latter fields.

Radioisotopes are being supplied in increasing numbers, as indicated by data available from the Operations Division of the Oak Ridge National Laboratory (3). In Georgia, six establishments have been or are receiving radioisotopes: Camp Steel Works, Emory University, Georgia Experiment Station, Public Health Service in Savannah, Medical College of Georgia, and the University of Georgia School of Medicine (4). The isotopes shipped to date have included 6 curies of Co^{60} (metal), 23 units of Na^{24} of approximately 15 millicuries (mc.) per unit, 2 curies of I^{131} , 100 mc. of P^{32} , and 5 microcuries ($\mu\text{c.}$) of Cl^{38} (4). Of a total of 1,299.5 curies shipped from the Oak Ridge National Laboratory to non-AEC users from August 1946 through December 1950, a little over 8 curies have been shipped into Georgia.

Hazards

The potential hazards resulting from the use and discharge of these radioisotopes under conditions which exist in Georgia are considered here.

However, the principles and techniques described may be used for evaluating the hazards in any given geographic area, and are not restricted to conditions in Georgia.

External

Cobalt-60 (metal) will not be discharged as a waste. However, unless suitable precautions are taken to protect personnel from its ionizing radiations, it may be hazardous. The tech-

nique used in evaluating and reducing the external radiation hazard is illustrated by the following example.

One decay scheme that has been given for Co^{60} (5) shows that one beta particle and two gamma quanta are given off in cascade per disintegration. Neglecting the beta radiation, a curie of this isotope will emit quanta of each energy which are equivalent to 1 curie. Substituting in the approximate expression

$$R_1 = 6 C E$$

where

R_1 = dosage rate in roentgens per hour (r./hr.) at 1 foot

C = number of curies of radioisotope emitting the gamma radiation (assuming 3.7×10^{10} disintegrations per second to be 1 curie)

E = gamma energy in million electron volts (Mev) per disintegration. Co^{60} has gamma energies for 1.1 and 1.3 Mev in cascade.

Then for a 6-curie source

$$R_1 = 6 \times 6 \times (1.1 + 1.3) = 86.4 \text{ roentgens/hour (r./hr.) at 1 foot.}$$

If we assume a dose rate of 0.04 r./week for a 40-hour week, then

$$\frac{0.04}{40} = 0.001 \text{ r./hr. or 1 milliroentgen per hour (mr./hr.).}$$

The 6-curie source of Co^{60} , therefore, gives

$$\frac{86.4 \text{ r./hr.}}{0.001 \text{ r./hr.}} = 86,400$$

times the permissible dose rate at the 1-foot distance. The thickness of lead shield required to reduce the dose rate to 0.001 r./hr. may be found by means of the expression

$$I = I_0 e^{-\mu t} \text{ or } \log \frac{I_0}{I} = 0.434 \mu t$$

where

I_0 = initial intensity

I = final intensity

μ = linear absorption coefficient taken as 0.65 cm.^{-1} for lead and for 1.3 Mev gamma energy

t = thickness of absorber in cm.

The thickness of lead required for shielding will be 17.5 cm. or 6.9 inches.

To determine the dose rate at any distance other than 1 foot the inverse square law is applied. For example, if the external radiation at 1 foot is 86.4 r./hr., at 2 feet it will be $\frac{86.4}{(2)^2}$

Table 2. Characteristics of radioisotopes shipped into Georgia

Radioisotope	Suggested MPC value $\mu\text{c}/\text{cc.}^1$		Radio- active half-life ²	λ Decay constant ³ sec.^{-1}	Mg./curie ⁴	MPC Mg./liter ⁵
	In air	In water				
(1)	(2)	(3)	(4)	(5)	(6)	(7)
I^{131} -----	3×10^{-9}	3×10^{-5}	8.0 d	1×10^{-6}	0.81×10^{-2}	2.43×10^{-10}
P^{32} -----	1×10^{-7}	2×10^{-4}	14.3 d	5.59×10^{-7}	3.52×10^{-3}	7.04×10^{-10}
Na^{24} -----	2×10^{-6}	8×10^{-3}	14.9 h	1.29×10^{-5}	1.14×10^{-4}	9.1×10^{-10}
Cl^{36} -----	4×10^{-7}	2×10^{-3}	$4.4 \times 10^5 \text{ y}$	4.99×10^{-14}	4.42×10^{-4}	8.84×10^{-2}
Co^{60} -----	1×10^{-6}	2×10^{-2}	5.2 y	4.23×10^{-9}	0.87	1.74×10^{-5}

¹ Morgan data.

² From National Bureau of Standards Circular NBS-499.

³ $\lambda \text{ seconds}^{-1} = \frac{0.693}{\text{half-life in seconds}}$

⁴ $3.7 \times 10^{10} \text{ disintegrations per second} = \frac{0.693}{T (\text{half-life in days})} \times \frac{W (\text{gm./curie})}{A (\text{atomic weight})} \times 6.02 \times 10^{23} (\text{Avagadro's number})$.

Therefore, $W (\text{gm./curie}) = 7.67 \times 10^{-9} \text{ AT}_D$ or $W (\text{mg./curie}) = 7.67 \times 10^{-6} \text{ AT}_D$.

⁵ $\frac{\mu\text{c}}{\text{cc.}} \times 10^{-6} \times 10^3 \frac{\text{cc.}}{\text{liter}} \times \frac{\text{mg.}}{\text{curie}}$; MPC value for water $\times \frac{\text{mg.}}{\text{curie}}$ value $= 10^{-3} \times 3 \times 10^{-5} \times 0.81 \times 10^{-2} = 2.43 \times 10^{-10}$.

or 21.6 r./hr., at 3 feet it will be $\frac{86.4}{(3)^2}$ or 9.6 r./hr., etc.

These calculations may be applied only when a point source of gamma activity is under consideration.

Internal

The remaining substances, I^{131} , P^{32} , Na^{24} , and Cl^{36} , could conceivably be discharged into the sewerage system after use as therapeutic agents or in research. These substances have MPC values in water or air as indicated in table 2. These values indicate that with the exception of Cl^{36} and Co^{60} the amounts dealt with are exceedingly small—quantities of the order of 10^{-10} parts per million (ppm). Concentrations in terms of ppm and ppb (parts per billion) are well known to public health personnel, but these for radioactive substances may be 10 million times lower. The amount of radioactive material which represents 1 curie of each of these substances is also indicated in table 2.

Some sample calculations follow which indicate the methods that may be used for estimating the degree of hazard resulting from the use and disposal of radioisotopes. The examples will be confined to radioisotopes that

have been shipped into Georgia. In the initial calculation the following assumptions were made:

1. The activity is assumed constant—no decay. Actually, the radioactive decay of the isotope is not negligible, as will be shown later for I^{131} .

2. The radioisotope is discharged completely—no loss through usage. Again this effect may not be negligible and will be illustrated in the case of I^{131} .

3. Each radioisotope acts independently.

4. All radioisotopes, with the exception of the Co^{60} (metal), are received and discharged in 1 week.

If the number of millicuries of each radioisotope is divided by the tentative MPC value for that radioisotope in water or air, a value in terms of volume is obtained:

$$\text{Millicuries} \times \frac{\text{cubic centimeters}}{\text{millicuries}} = \text{cubic centimeters.}$$

This volume is equivalent to the dilution required to make the given amount of radioisotope innocuous (innocuous in the sense that no detectable injury, based on our present knowledge, will result from continuous exposure to the radioisotope).

Table 3. Dilution required to reduce amount of radioisotope shipped to tolerance

Radioisotope	Amount shipped	Dilution required		
		Cubic centimeters	Metric tons	Million gallons
I^{131} -----	2 curies-----	$\frac{2 \times 10^6 \mu c}{3 \times 10^{-3} \mu c/cc} = 0.67 \times 10^{11}$	0.67×10^5	17.7
P^{32} -----	100 mc-----	$\frac{100 \times 10^3}{8 \times 10^{-4}} = 0.50 \times 10^9$	0.50×10^9	0.13
Na^{24} -----	23 units at 15 mc./unit-----	$\frac{23 (15) \times 10^3}{2 \times 10^{-3}} = 0.44 \times 10^8$	0.44×10^3	0.01
Cl^{38} -----	5 μc -----	$\frac{5}{2 \times 10^{-3}} = 0.25 \times 10^4$	0.25×10^{-2}	-----
Total-----	-----	-----	-----	17.84

The volumes of water required to dilute the wastes to the MPC values given in table 2 are determined as indicated in table 3. These calculations show that approximately 17.84 million gallons of water would be required to dilute to the MPC value all of the radioisotopes except Co^{60} (metal) shipped into Georgia. This volume of water is slightly greater than the volume of water—about 14 million gallons per day (mgd)—supplied daily to the inhabitants of Savannah (6). With uniform discharge throughout the week, approximately 2.55 mgd would be required for dilution, or a stream having a discharge of approximately 4 cubic feet per second would suffice when radioactive decay is not considered.

The example cited above shows that it is possible to reduce the activity to the MPC value by diluting with water. Another method of dilution proposed is that of isotopic dilution. In isotopic dilution a carrier having chemical characteristics identical to those of the radioactive substance itself is added. The method is based upon the principle that the body (or any living form) does not distinguish between isotopes of the same element. Hence, since it can accept only certain concentrations of a specific nontoxic substance, excesses will be excreted or discharged, and the radioactive form of an element may be diluted with its stable isotope to such a concentration that when taken into the body the amount of the radioactive form retained will be below the maximum permissible concentration. This is one possible

means of reducing concentration by lower forms of plant or animal life. Isotopic dilution generally is not required and in most instances is not practical.

Discharge of I^{131} From Hospitals

The effect of decay will now be taken into account. For purposes of illustration, assume that a hospital in Savannah receives 100 mc. of I^{131} for hyperthyroid and cancer therapy, and that a portion of this material will be discharged along with the wastes from the hospital. According to Butrico (7) large quantities of iodine are excreted from the kidneys after administration, and close to 100 percent of a large dose may be found in the urine over a period of several days. He reports that other investigators found that over a 5-day period normal individuals had urinary excretions of 80 percent of the administered dose. It may be stated that with most patients approximately 50 or 60 percent of the administered dose is excreted in the first 24 to 48 hours. These urine wastes constitute the bulk of the radioactive wastes resulting from the use of I^{131} .

If we assume that 100 mc. of I^{131} are given to a patient at time zero and that 55 mc. of I^{131} are discharged in the urine during the first day, a curve indicated by the heavy solid line in figure 1 is obtained. This shows that during the first day 8.5 percent of the I^{131} was lost through decay, and that with a discharge of 55 mc. in the urine the patient retained 36.5

Figure 1. Disposal of I^{131} from a hospital.

mc. of I^{131} . If we assume that 55 mc. of activity are discharged in 48 hours (simplified here to show all discharge—heavy dash line—on the second day) the patient retained 29 mc. of the I^{131} , since 16 percent of the activity is lost through decay. The amount of activity retained by the patient will decrease by decay as shown by the curves. Decay will reduce the 55 mc. of iodine discharged as shown by the dot-and-dash line, so that after 1 day about 50 mc. will remain, after 2 days about 46 mc., and after 8 days, 27.5 mc. The amount of water required to reduce the 55 mc. of I^{131} to the tolerance concentration of $3 \times 10^{-5} \mu\text{c}/\text{cc}$. will be approximately 0.5 million gallons (mg.). If the 55 mc. of I^{131} are discharged from a 1,000-bed hospital there would be available for dilution only about 200,000 to 400,000 gallons per day of sewage. Therefore, the sewage would contain 1.25 to 2.5 times the maximum permissible concentration of I^{131} , if discharged uniformly throughout the day. This activity would be diluted further by the flow in the sewer. With I^{131} , because of its short half-life, 8 days, there is little likelihood of any radiation hazard.

Disposal of I^{131} by Sewage Treatment

Let us trace the sewage containing I^{131} through the sewer to its ultimate point of discharge—directly to a receiving stream or after passage through a sewage treatment plant. The raw sewage solids will take up some of the radioactive iodine, perhaps up to 20 percent (8). Bacterial slime on the sewer wall may also account for the removal of additional amounts of radioiodine. If no sewage treatment plant is available, the wastes containing the 55 mc. of activity noted above (reduced by an amount for decay) will be discharged into the stream as shown by line *A-F-G* in figure 2. The effect of various sewage treatment processes is illustrated in somewhat simplified form. Note the change in horizontal scale after 0 to 1 days.

If primary treatment alone is provided, the activity will be reduced by decay and sedimentation only, as shown by *O-A-B*.

O-A. Travel time in the sewerage system before entering the sewage treatment plant. The loss here is due to decay only.

A-B. Removal of radioactive material taken up by suspended solids removed by the primary settling basin. The position of point *B* is found as follows: 20 percent of the I^{131} is taken up by the suspended solids and 60-percent removal of suspended solids is attributed to sedimentation.

B-On. The effect of decay beyond *B* is shown by *B-O* and the dotted line.

If the plant includes primary sedimentation and trickling filters, the activity will be reduced as follows:

O-A. Travel time in the sewerage system before entering the sewage treatment plant. The loss is due to decay only.

A-B. Removal of radioactive material by the primary settling basin. See *A-B* above.

B-D. Removal by trickling filter operating at rate of 2 million gallons per acre per day. Studies by Carter (9) indicated 85-percent removal by filter and secondary sedimentation.

D-On. Loss in effluent due to natural decay. In 20 days' time the activity will have been reduced to about 2.4 percent.

If the plant is of the activated sludge type with primary sedimentation, aeration, and secondary sedimentation, removals as indicated by the dash line in figure 2 may be obtained.

Figure 2. Removal of I^{131} by sewage treatment processes.

- O-A. Loss due to decay.
 - A-B. Removal by primary sedimentation.
 - B-C. Loss due to decay during 12-hour aeration period.
 - C-E. Loss due to removal of suspended solids in secondary clarifier, assuming 95-percent removal of initial activity (8).
 - E-On. Loss by decay.
- Note change of horizontal scale after 0 to 1 day.

The sludge which accumulates from primary and secondary sedimentation may be digested and the activity contained therein will reduce according to the dot-and-dash line. Point *F* indicates the percent reduction in activity following 30 days' digestion and point *G* represents additional decay due to 7 days' drying on sand beds. If the sludge is stored, activity will decrease as indicated beyond point *G*.

Other treatment processes have been suggested for different radioisotopes. The methods that have been investigated include evaporation, co-precipitation, ion exchange, biological processes, metallic displacement, sand filtration, and crystallization. Until the use of radioisotopes becomes much more widespread, or reactors are built for power or other purposes,

the radioactive waste disposal problem probably will be a minor one in most States.

Removal of I^{131} and P^{32} by Water Treatment Processes

Let us now consider what takes place when a stream which contains I^{131} or P^{32} is used as a source of water supply (fig. 3). In this case assume that 2 weeks' storage is provided in a reservoir before treatment and the plant includes orthodox coagulation, settling, and filtration. Consider first a source containing I^{131} .

Two weeks' storage will reduce the activity to that represented by point *B*. If alum coagulation is used along with sedimentation and filtration no appreciable removal of I^{131} (less than 0.4 percent) will be obtained (10). However, the addition of small amounts of carbon, copper, or silver may increase removals to 75 percent. This removal is indicated by point *C*. Chlorination and storage have no effect on removal, although there will be some reduction due to decay as shown by the heavy solid line beyond point *C*.

Figure 3. Removal of I^{131} and P^{32} by water treatment processes.

If the surface source of supply contains P^{32} , which has a half-life of 14.3 days, 2 weeks' storage will reduce the activity to the value indicated for point A. Alum coagulation, settling, and filtration will account for a removal of 96 to 98 percent (10), which reduces the activity to the value shown at D. Beyond this point decay will account for additional reductions as indicated by the dash line.

Mixtures of radioisotopes may or may not be removed, depending upon the radioisotopes comprising the mixture. Mixed fission products activity, for example, may be reduced by approximately 50 percent by coagulation and settling, and filtration may increase removals to 70 percent (8).

At this time a point should be discussed which is obvious to many but may be somewhat confusing to some and that has to do with percent removal. The percent removal has little significance unless one knows the original concentration of radioactive material. If, for example, a waste contained an I^{131} concentration of 1 mc./cc., it would be necessary to obtain a removal of 99.99997 percent to reduce the original I^{131} present to the MPC. If our processes will effect a 95-percent reduction, the highest initial concentration of I^{131} that would be permissible in order to meet these requirements after treatment would be 6×10^{-4} $\mu\text{c}/\text{cc}$. Any concentration greater than this would result in an effluent containing concentrations in excess of the MPC values.

Explosion of a nuclear bomb will result in the release of considerable amounts of radioactivity. The effect of this on the water supply will depend upon the nature of the blast and atmospheric conditions at the time of the blast. Georgia is perhaps a little more fortunate than many States with respect to contamination of surface water supplies following a nuclear explosion, since about 30 percent of the population served by public water supplies use ground water sources of supply. Approximately 66 percent of the public water supplies are from deep wells (6). There is little likelihood that these would become contaminated during an emergency, and they should serve as a source of supply if the distribution systems are not destroyed or damaged.

Concluding Statement

With the emphasis that is being placed on civil defense activities at present, much has been said about the need for providing facilities for measuring radioactivity. This equipment is rather expensive and may even be in relatively short supply. It is my personal belief that much can be accomplished now through the cooperative use of existing facilities in hospitals and research centers to familiarize public health personnel with the techniques of counting, sample preparation, and measurement of radioactive materials. Such cooperative effort will permit water and sewage treatment plant operators to determine for themselves the amounts of radioactive materials that are being discharged into sewerage systems and water courses and to evaluate the possible potential hazard from this discharge.

ACKNOWLEDGMENT

The author acknowledges the assistance of Dr. K. Z. Morgan, for granting permission to use the data in table 1; of the Operations Division of the Oak Ridge National Laboratory, for data on radioisotope shipments; and of Dr. Elda E. Anderson and Dr. Forrest Western, for review of the material and for their suggestions. The work described in this report was performed at the Oak Ridge National Laboratory for the Atomic Energy Commission under contract No. W-7405-Eng-26.

Excess Mortality From Influenza and Pneumonia

Excess mortality from influenza and pneumonia is used as the best available measure of epidemic periods and of the size and importance of an epidemic. The chart shows the excess mortality per 100,000 population during the whole of each epidemic in groups of cities in the United States, 1918 to 1951.

The decrease in excess mortality may be related to one or more of several things: (1) The mortality of diseases designated as influenza may be decreasing by reason of change in what is now diagnosed as influenza, because of recently acquired knowledge of the etiology and the early clinical manifestations of the disease; (2) influenza fatality may be decreasing by reason of (a) greater natural immunity ac-

quired by more individual contact with the disease because of greater movement of the population; (b) milder strains of the virus becoming widespread; or (c) more successful treatment of influenza and its most frequent complication, pneumonia, by the use of the newer chemotherapies.

Aside from epidemic peaks, the death rate from influenza and pneumonia in the United States decreased from roughly 200 per 100,000 in 1900 to 100 in 1937, when the trend turned sharply down, to about 35 in 1950. (See "Trends and Epidemics of Influenza and Pneumonia, 1918-51," by Selwyn D. Collins and Josephine Lehmann, *Public Health Reports*, Vol. 66, No. 46, November 16, 1951.)

Bait Shyness to ANTU

In Wild Norway Rats

By T. B. GAINES and W. J. HAYES, Jr., M.D.

In spite of the fact that certain deficiencies limit the usefulness of alpha-naphthyl thiourea (ANTU) as a rodenticide under operational conditions, it is safe and, when used infrequently, effective in controlling populations of Norway rats.

No controlled study appears to have been made on the persistence of tolerance and/or bait shyness to ANTU under field conditions. Therefore, the present study was conducted to determine what effect ingestion of a sublethal dose of ANTU would have on the subsequent acceptance of the poison by Norway rats and their intoxication by it. Laboratory and simulated field studies were made. In each instance, the rats had available a supply of wholesome food, so that they were not limited to the dilemma of poison or starvation.

The use of ANTU as a rodenticide was developed by Richter (1) during World War II. The compound differs from other common rodenticides in its relative specificity for Norway rats; it is essentially ineffective against roof rats, and impractical for their control. However, its use has been advocated on the basis of effectiveness and safety (2). Although the compound is highly toxic to pigs, to cats, and especially to dogs, it is significantly less toxic to many other species of domestic animals, and it is estimated that man also is highly re-

sistant to the poison (1, 3, 4). Before the introduction of warfarin, ANTU was considered the safest rodenticide, with the exception of red squill (5).

Richter (6) demonstrated in the laboratory that Norway rats with no choice of wholesome food developed a tolerance and refusal response for ANTU-poisoned bait which persisted, in general, less than a month. The persistence of tolerance and/or bait shyness for a month under field conditions would present a distinct but minimal disadvantage. Actual field experience (2) has shown that this disadvantage of ANTU may be important if the compound is used more often than once a year on the same premises.

Materials and Methods

The technique used for collecting and maintaining wild Norway rats was the same as that described in an earlier article (7). The procedure for the laboratory, as well as for simulated field studies, was to give the rats a sublethal dose of ANTU in bait and, after an interval, to test the reaction of the rats to the same poison in the same bait (group I). Two kinds of control groups were used: group II, those which were sublethally poisoned and later were offered ANTU in a different bait from that used for the sublethal dose; and group III, those which had had no previous experience with the poison whatever.

In giving the sublethal dose, it was considered highly important to have the rats take it voluntarily so that the conditions of the experiment would resemble those of the field

Mr. Gaines is a biologist and Dr. Hayes is a senior surgeon assigned to the technical development branch of the Communicable Disease Center, Public Health Service, Savannah, Ga.

as closely as possible. To accomplish this, ANTU was mixed in yellow corn meal (maize) at the rate of 0.1 percent by weight (1 mg./gm.). This bait was then weighed out individually for each rat used in laboratory experiments, in such a way that if the rat ate its entire portion it would consume 6 mg. of ANTU per kilogram of body weight (rats tested after 1 or 2 weeks) or 5 mg./kg. (rats tested after 1, 2, and 3 months). Rats which failed to take the entire portion within a 2-day period, as well as those which died as a result of the dose, were discarded. Rats which ate the poisoned corn meal properly were placed in stock cages and held on a diet of Purina Laboratory Chow for the appropriate number of weeks or months before testing.

All poison bait used either for the "sensitizing" dose or for the final tests in the laboratory or in the field was thoroughly mixed for 15 minutes with an electric food mixer. In the laboratory, all bait was fed in nonspillable food cups to rats individually caged in Army Medical School-type cages. During the actual tests, each rat was offered a choice of a weighed ANTU-poisoned bait and another bait which was identical except for the omission of ANTU. The baits were exposed for 2 days, after which they were reweighed and the consumption was computed. Surviving rats remained under observation for a week after the poison was removed; they were not reused for a second test.

The simulated field tests were conducted in a manner basically similar to that used in the laboratory. Rats were housed in wooden, barracks-type buildings, measuring about 20 by 100 feet. These buildings were ratproofed and supplied with ample harborage, consisting of boxes, paper, and other rubbish. Each building was artificially infested with rats at least 6 weeks before the tests were started. Before and during the test periods the rats were maintained with liberal supplies of corn meal and wheat shorts as well as water.

The ANTU-poisoned bait was distributed in the buildings in patches of approximately a heaping teaspoonful each near the harborage and along the runways. It was left exposed to the rats for 2 days and then was removed by sweeping. No attempt was made to determine the amount of bait consumed in the buildings.

Two to three days later, the harborage was removed piece by piece; the dead rats were picked up and all the survivors were caught by hand in the empty room. Rats which survived the poisoning were then returned to the building, and the harborage was returned each time until the study was completed. The original sensitizing dose was given by offering ANTU in ground laboratory chow at a concentration of 0.1 percent by weight.

The simulated field tests differed from those in the laboratory in the following ways:

1. There was no assurance that every rat which survived the sensitizing dose of ANTU actually took any of the compound.

2. The sensitizing dosage of ANTU consumed by rats in the barracks-type buildings undoubtedly varied considerably on a milligram-per-kilogram basis. It was considered more valuable to simulate field conditions closely than to use an exact dosage.

3. In the 2-, 3-, and 4-month tests, some immature rats never had an opportunity to encounter a sensitizing dose of ANTU before they received the final dose.

4. Certain adult rats in the later simulated tests had more than one opportunity to take a small sensitizing dose. (The duration of bait shyness was measured from the last sensitizing exposure.)

After the sensitizing dose had been given, all rats in laboratory or simulated field experiments, except those tested in the laboratory after only 1 week, were offered ANTU at a concentration of 2.0 percent by weight. The latter animals received 1.0 percent ANTU, but the mortality of the controls was considered too low. Consequently, the higher concentration of poison was adopted for the remainder of the experiment. Concentrations of 1.0 to 5.0 percent are commonly recommended for field use.

Results

Laboratory Tests

The results of the laboratory studies are presented in table 1. Test animals had previously ingested ANTU in corn meal at a dosage of 5 mg./kg., except those held 1 and 2 weeks, which ingested ANTU at a dosage of 6 mg./kg. Group III rats were previously untreated. The

mortality (6 to 33 percent) among group I rats previously poisoned by ANTU in the same bait is significantly different from the mortality (54 to 94 percent) among group III rats used as untreated controls. The fact that the previously treated rats which were offered ANTU in corn meal in these tests generally took a larger proportion of their total food from the poison-free bait than did rats in group III indicates that the specific ANTU-bait combination was detected by the group I rats. Furthermore, among the same previously poisoned rats there was not much difference in the percentage of those which refused poisoned bait and those which refused poison-free bait, suggesting that the refusal response was partially directed at the corn meal as such, although the possibility that the refusal of unpoisoned bait may have been caused by illness induced by eating the poison must be considered, as shown by Richter (6).

There was some advantage in using an alternate bait against previously poisoned rats, although the mortality (group II, 33 to 71 percent) was generally less than among rats used

as untreated controls (group III, 54 to 94 percent). These results suggest that Norway rats detect ANTU as such and are not entirely dependent for their protection on an association between previous illness and a particular kind of food (in this instance, corn meal).

In the laboratory tests, bait shyness did not appear to increase or decrease when tested at intervals of 1 and 2 weeks and 1, 2, and 3 months. Under the conditions of the experiment, bait shyness lasted for an undetermined period greater than 3 months.

The actual consumption of ANTU was computed individually for each rat on a milligram-per-kilogram basis. A review of these figures showed that, on the average, rats previously exposed to ANTU were killed by the same small dosage which killed the previously unexposed controls. There was, then, no evidence for the presence of tolerance. It should be recalled, however, that the experiment was not designed for the study of tolerance, and its presence, as a minor factor, is not excluded.

Simulated Field Tests

The experimental design and summary of tests conducted with ANTU-poisoned bait against wild Norway rats living under simulated field conditions from March 31, 1949, to February 6, 1950, are presented in table 2. All rats had been in their respective buildings at least 6 weeks before they were exposed to ANTU. A breakdown of the same data for adult and immature rats is given in table 3. The mortality among all rats previously offered ANTU in the same bait was very low (group I: 0.0 to 47.7; average 15.3 percent) as compared with the mortality among rats used as untreated controls (group III: 50.7 to 80.0; average 68.1 percent). The use of different bait against rats of group II previously exposed to ANTU gave a mortality of 2.9 to 23.4 percent (average, 16.2

percent). This result confirms the presence of bait shyness to ANTU, but it fails to support the idea that this bait shyness is augmented when the poison is presented a second time in the same bait. Although the figures differ, the result is the same whether one considers the entire populations or only the adult rats which were tested.

Bait refusal among rats previously exposed to ANTU persisted unchanged for at least 4 months from the time they were last exposed.

As expected, the percentage mortality was much greater among adult rats than among immature rats (table 3). Riechter (6) has estimated that young rats are six to seven times more resistant than adults.

It may also be noted that, although the present experiments were not designed to test the importance, which has been noted by others, of

season (8) or temperature (9) on the susceptibility of Norway rats, no effects correlated with season or temperature were noted.

Discussion

In the use of ANTU as a rodenticide one encounters the problem of bait shyness (secondary bait refusal). This study has shown that such shyness lasts at least 4 months under simulated field conditions. As already mentioned, Emlen reported that poor control may result if ANTU is used more than once a year on the same premises. Following control estimated at 85 to 90 percent, essentially isolated populations recover in 15 to 44 months, or at a rate of 2 to 6 percent per month (2, 10). Under these circumstances, a large proportion of the rats present 1 year after the use of ANTU would be young adults which had never been exposed to the compound. Present field and laboratory experience cannot, therefore, rule out the possibility that bait shyness to ANTU in the Norway rat lasts more than a year, or even for the lifetime of the individual rat.

Regardless of the method by which ANTU is used, it must be recognized that there is a wide variation in its effectiveness against immature and against adult Norway rats (1, 4).

Its unsuitability for roof rats has already been mentioned.

What, then, is the status of ANTU in rat control? Its various deficiencies should not mask the facts that (a) when properly used for the first time against populations of Norway rats it gives rapid and acceptable control, and (b) among quick-acting rodenticides it has a good record of safety under conditions of actual use.

The use of ANTU or any other rodenticide should be accompanied by appropriate rat-proofing and sanitation. Destruction of the remnant of population left after the use of any quick-acting rodenticide may best be accomplished by using a different poison. However, like ANTU, other quick-acting rodenticides induce bait shyness to some extent, and their value for repeated use is thus limited. Except for red squill, which is a relatively ineffective compound, none of the quick-acting materials offer the same degree of safety as does ANTU. The advantages of warfarin for eliminating the remnants of larger populations, or for maintaining what has been called chemical ratproofing, have recently been pointed out (7).

The failure of this study to demonstrate the presence of tolerance does not constitute any contradiction of earlier work on this phenome-

non. It does suggest that, under actual field conditions, bait shyness is a much more important factor than is tolerance in determining the outcome of control operations with ANTU. The study thus establishes a clear reason for the failure of ANTU to control Norway rats when used at too-frequent intervals.

Summary and Conclusions

1. Under laboratory conditions and with a free choice of food, Norway rats retained bait shyness to ANTU for 3 months following a single dose of it at the rate of 5 mg./kg.

2. Under simulated field conditions, bait shyness was demonstrated 4 months after the last exposure to ANTU. The time at which this reaction might eventually decrease was not determined.

3. Tolerance was not demonstrated, but, because of the nature of the tests, this result was not considered to rule out the presence of tolerance as a minor factor.

4. Bait shyness was considered a major factor limiting the usefulness of ANTU under operational conditions.

5. In spite of its deficiencies, ANTU presents the advantage of safety and, when used for the first time against populations of Norway rats, the advantage of effectiveness.

Renewed Efforts To Uncover Scrap Metal Urged

Defense Mobilization Director Charles E. Wilson has urged increased efforts to uncover supplies of metal scrap urgently needed by the Nation's mills and foundries so that maximum steel production might be maintained. Industry, business institutions, government agencies, and other organizations are requested to redouble their efforts to increase the flow of dormant scrap to the mills.

The Public Health Service, as that agency of the Federal Government most closely associated with health departments and hospitals of the country, has been asked to bring to the attention of these organizations the pressing need for scrap metal and to request an intensification of the effort to increase supplies.

Hospitals, health departments, and other agencies and institutions can aid materially in the drive by continually surveying their installations for obsolete and worn-out machinery and equipment and disposing of such items to local scrap dealers.

Public Health Service hospitals and installations have been directed to cooperate to the fullest extent possible in the drive.

HOSPITAL BEDS

in the UNITED STATES

The Nation had over 1,000,000 acceptable hospital beds in 1951, in addition to about 190,000 beds in Federal Government hospitals, as shown by a summary of State hospital plans developed under the Hospital Survey and Construction (Hill-Burton) Act of 1946.

These plans define and identify acceptable beds and also provide an estimate of hospital bed needs. They show that adequate hospital care for the people of this Nation requires 874,000 more beds. Currently, 54 percent of the Nation's estimated hospital needs are being met by the present supply of acceptable hospital beds.

Assuming quality patient care, hospital beds may be regarded as symbols reflecting facilities for patient care. Present bed supply levels and needs for more facilities as of 1951 are summarized by major categories in the above chart.

Unmet Bed Needs

Most of the recent new construction has been general hospitals. This is reflected in the figures for the per-

cent of total needs met by existing general hospital beds in 1948 compared with 1951. In 1948, 41 percent of general hospital bed needs were unmet. In 1951, 33 percent of the general hospital bed needs were unmet.

Construction of new chronic and mental beds just kept pace with needs due to population increase and the replacement of beds unsuitable for use. Two-thirds of the Nation's estimated 874,000-bed deficit is accounted for by the need for providing care for patients with chronic and mental illness. These two categories alone total 587,000 needed beds.

The number of beds suitable for providing tuberculosis hospital care, according to the Hill-Burton standard, has progressively increased. In 1951, 85,000 suitable tuberculosis beds were available, and about 55,000

more were needed. The criterion for determining tuberculosis bed needs differs from that used in determining general, chronic, and mental bed needs. Annual deaths from tuberculosis in a State are used rather than a population basis, as in the case of the other groups.

Early diagnosis and improved treatment methods for tuberculosis have increased the length of patients' lives. The need for beds for tuberculous patients is therefore increasing rather than decreasing. A better standard for determining tuberculosis bed needs, based on reliable morbidity data, is needed. Until such data are available, prevalence rates offer a means for estimating more adequately goals for the construction of hospital facilities for the treatment of the tuberculous.

Bed Needs of the States

These data are for the Nation as a whole. What about the States? Do hospital needs differ between States and within a State? Fortunately, State plans include a con-

This report was prepared by the Division of Hospital Facilities of the Bureau of Medical Services, Public Health Service.

tinuous inventory of existing hospital beds with an indication of their suitability for use as determined by each State.

The Hill-Burton standard, as set by Title VI of the Public Health Service Act, is: 4.5 to 5.5 beds per 1,000 population for general hospital construction, depending upon population density; 5 beds per 1,000 population for the mental diseases; 2 beds per 1,000 population for the chronic diseases; and 2.5 beds per average annual deaths from tuberculosis over a 5-year base period.

No State has yet met the Hill-Burton standard in all four bed categories. Only three States have met or exceeded the standard in the general bed category. These are, however, States where population densities are low. Despite the apparent meeting of general hospital bed needs on a state-wide basis, there are still large areas within these States where needs have not been met. Existing beds are either concentrated in a few areas or the population distribution is such that many people still do not have access to hospital facilities.

The state-by-state record of existing acceptable hospital beds at the end of 1951 is shown in the accompanying table, together with ratios for the continental United States.

The effect of the existing standard on meeting needs for beds for tuberculous patients is reflected in the fact that seven States are shown as either having met or exceeded the standard.

The need for hospital beds for patients having mental and chronic diseases is reflected in the low ratios reported by many of the States.

Hill-Burton Construction

In 1946, with the passage of the Hospital Survey and Construction Act, the country was provided with a systematic, nation-wide hospital construction program utilizing financial aid from the Federal Government.

The program first aims to assist States in determining their need for hospital and health center facilities and in planning for the provision of needed facilities. Second, it assists the States in carrying out these plans by financial aid for the construction

Medical Group Practice In the United States

The data in this publication were obtained from a survey initiated by the Public Health Service in 1945 and conducted with the cooperation of most of the medical groups in the country. The report is a summary of recent published material and supplementary unpublished data on fees and volume of work. It is largely restricted to the quantitative aspects of medical group practice. It deals with the development and trends of group practice, reporting on personnel and organization, administration, income, prepayment plans, fees, and volume of work. The statistical material is based upon a questionnaire survey of all listed medical groups in the United States in 1946, an intensive study of 22 selected medical groups, and an additional 80 groups which were visited briefly.

Hunt, G. Hulsey, and Goldstein, Marcus S.: *Medical Group Practice in the United States*. (Public Health Service Publication No. 77.) 1951. 70 pages. From the Superintendent of Documents, Government Printing Office, Washington 25, D. C., 25 cents.

The National Health Survey, 1935-36—Scope, Method and Bibliography

(Continued interest in the National Health Survey of 1935-36, and requests for information on the methods used in its house-to-house canvass of some 700,000 households, have made it necessary to reissue "The National Health Survey; Scope and Method of the Nation-Wide Canvass of Sickness in Relation to Its Social and Economic Setting." This paper, which was first published in *Public Health Reports* in 1939, comprises part I of this new publication. Part II is a comprehensive list of references, briefly annotated, to

some 180 reports and articles which present descriptions or findings of the survey and which have been published over more than a decade in many different journals and bulletins.

...

The National Health Survey, 1935-36—Scope, Method, and Bibliography. Public Health Bibliography Series No. 5. (Public Health Service Publication No. 85). 1951. 67 pages. From the Superintendent of Documents, Government Printing Office, Washington 25, D. C., 30 cents.

Monthly Vital Statistics Report

The *Monthly Vital Statistics Report*, a new publication of the National Office of Vital Statistics, Public Health Service, will replace three current publications, *Monthly Marriage Report*, *Monthly Vital Statistics Bulletin*, and *Current Mortality Analysis*. Starting with data for January 1952, it will contain monthly and cumulative figures on births, marriage licenses, deaths, and infant deaths for States, certain cities, and Hawaii, and on marriage licenses for major cities, with a brief analysis of these vital statistics. The first issue will carry divorce data for a limited number of States and Hawaii, starting with figures for December 1951.

In addition, the new report will contain death rates by cause, age, race, and sex estimated from the returns of a 10-percent sample of death certificates filed in State and independent city vital statistics offices. The first issue will present these preliminary death rates for the United States for December 1951 and the year as a whole, with an analysis of current mortality conditions.

Volume 1, No. 1, of the new series will be published in March 1952.

The mailing lists of the three merging periodicals are being combined for the new *Monthly Vital Statistics Bulletin*. Requests to be placed on the lists should be addressed to the National Office of

Vital Statistics, Public Health Service, Washington 25, D. C. Requests should include a statement as to how, by whom, and to what extent the publication will be utilized.

Cancer Morbidity Series

This series represents the first publication of comparative cancer morbidity data for 10 major cities in the United States. A decade ago the initial studies were published in *Public Health Reports*. The material was gathered during 1937-39. The data in the current series were collected during resurveys in 1947 and 1948.

The first three studies in the current series, published in 1950 and 1951, are on Atlanta, Ga.; San Francisco and Alameda Counties, Calif.; and New Orleans, La. The other seven cities under study include Birmingham, Ala.; Dallas, Tex.; Denver, Colo.; Chicago, Ill.; Detroit, Mich.; Pittsburgh and Philadelphia, Pa. The individual reports on each city will be followed by a United States summary.

Each report includes statistics on the number of cases reported and the completeness of reporting, and on the source and accuracy of reports. Incidence, prevalence, and mortality rates are given, as are relative frequencies by sex, age, and color. Figures are given on the stage of the cancer at diagnosis, time of hospitalization, mortality rates, survival prospects, and medical check-ups.

Meeting Problems of World Health

During the third national conference of the U. S. National Commission for United Nations Educational, Scientific, and Cultural Organization, a section meeting—one of 13 concerned with “major areas of cooperative effort for peace and security”—dealt with “Meeting World Health Problems.” *Public Health Reports* here presents the major papers of this symposium. This discussion, held in New York City, January 28, 1952, was planned in cooperation with the American Public Health Association, whose executive secretary, Dr. Reginald M. Atwater, was rapporteur for the section meeting.

The U. S. National Commission for UNESCO is required under Public Law 565 (79th Cong.) to “call general conferences for the discussion of matters relating to the activities of the United Nations Educational, Scientific, and Cultural Organization to which conferences organized bodies actively interested in

such matters shall be invited to send representatives . . .”

The first national conference was held in Philadelphia in 1947, the second in Cleveland in 1949. These conferences gave primary attention to UNESCO. The third conference, concerned with the relationship of the citizen to the United Nations system, was an effort of the National Commission to carry out the United Nations General Assembly resolution of November 17, 1947, relating to the UNESCO's role in educating about the United Nations.

Professor Winslow's introduction and the four symposium papers are presented in somewhat abbreviated form. Following each paper are a few questions as formulated by the American Public Health Association for the preparatory working paper. The opinions expressed are those of the authors and do not necessarily reflect the views of *Public Health Reports*, the Public Health Service, or those of the Federal Government.

The Global Problem: Inequality of Opportunity

By C.-E. A. WINSLOW, Dr.P.H.

The basic problem which confronts us in the building of a stable and peaceful world is the appalling inequality of opportunity which exists between the peoples inhabiting different areas of the globe.

One-fifth of the human race, living in the countries of Western Europe, North America, and the British Commonwealth, have, according to the most recent estimates, an annual income of \$461 per person per year and an average life span of 63 years.

Two-thirds of the human race, living in Africa, Southeast Asia, the islands of the Pacific, and Latin America, have a mean annual income of \$41 per person per year and an average length of life of 30 years.

This inequality is our really fundamental challenge. Even if there were no political and military rivalry between powerful nations, it would still make a unified world impossible. The issue of the rivalry which does exist will ultimately be decided by the strength of the appeal which totalitarianism and democracy can, respectively, make to the submerged two-thirds of the human race. Only if we can gradually improve the living conditions of the suffering peoples of Asia and Africa and the islands of the seas—and if we can do this, not as patronizing rich relations but in the spirit of constructive human brotherhood—can the world of tomorrow be soundly built.

Dr. Winslow is editor of the American Journal of Public Health and professor emeritus of public health at Yale University. He has recently returned from Geneva, where he prepared the volume, "The Cost of Sickness and the Price of Health," for WHO.

The problems of poverty and disease in underdeveloped areas are complex and interrelated. Men and women in these lands are poor because they are sick, and sick because they are poor. A coordinated approach to control of disease, increase in food supply, development of industry, and improvement in education, balanced to meet the needs of individual countries, offers the only sound solution of the problem.

The United Nations and its affiliated organizations face a challenge to build up national strength and prosperity in a positive sense. The efforts in this direction will have more fundamental and far-reaching results than efforts to check aggression and prevent worldwide conflict in a negative sense.

This task has been in large measure delegated to the United Nations Educational, Scientific, and Cultural Organization, and to other specialized agencies of the United Nations, such as the International Labor Organization, the Food and Agriculture Organization, and the World Health Organization. It is with the latter that we are concerned in the present discussion, never forgetting, however, that its work must be closely coordinated with that of other international service agencies.

It is the possibility of fostering sound local programs of health service in the underdeveloped areas of the world which will be primarily considered in the present discussion. The limitations on the process are obvious. In order to succeed, we must have:

A soundly planned program . . . adequate trained personnel . . . understanding and support of the population concerned . . . and essential financial support.

"The Spirit of the Symposium . . ."

"The problems of public health are relatively simple as compared with many other problems of international cooperation, but the successes so far attained may be encouraging to agencies dealing with more difficult areas.

"The spirit of the symposium on 'Meeting World Health Problems' was hopeful and confident. The view was expressed, for example, that in the year A. D. 2000, historians would look back on our mid-century as memorable for two of the most significant milestones in the history of the human race: the initiation

in Korea of the first exercise of world police power for the checking of armed aggression, and the development in the technical assistance and Point IV programs of a global responsibility for promoting by concerted international action the physical and emotional and social well-being of all the peoples of the earth."

—from a summary report to the U. S. National Commission for UNESCO, prepared by Dr. C.-E. A. Winslow, chairman of the symposium, and Dr. Reginald M. Atwater, rapporteur.

Meeting World Health Problems, 1

The Need for Sound Program Planning

By JOSEPH W. MOUNTIN, M.D.

The health task facing the world today is as vast and complex as it is important. If we are to make any inroads against the global burdens of disease, poverty, and ignorance, we need many things. We need, of course, the basic ingredients of men, money, and material. We need the incentive to progress that comes from popular understanding and participation. We need scientific knowledge, careful joint thinking and planning, effective organization, and high-caliber performance. Above all, we need soundly conceived health programs, suited to

Dr. Mountin, chief of the Bureau of State Services, Public Health Service, participated in the first meeting of the World Health Organization's Expert Committee on Public Health Administration, which convened in Geneva last December. This paper, prepared by Dr. Mountin, was read by Dr. L. L. Williams, Jr., chief of the Public Health Service's Division of International Health.

the problem, the time, and the place, and designed to move logically to attainable goals.

One of the first steps in planning sound health programs is to determine what is involved in the term "health" for various parts of the world. Actually, one of our main problems is that people are not always clear as to the meaning of health, especially in terms of the measures that organized communities might take to improve it. Health requirements vary from place to place. In one area, the apparent over-riding need is for the organization of sufficient medical and hospital services to care for acute illness; in another, health workers have to turn their attention to long-term diseases and mental disorders, and to the health problems of an aging population; in still another, the absence of simple community sanitation and personal hygiene may lie at the root of the health problem; and finally, in some places, the lack of food and the inadequacy of shelter are in themselves public health problems of paramount importance.

Moreover, the problems of health and disease do not exist in isolation but in varying combinations, depending upon a nation's stage of development. Many of them are woven into the socioeconomic and cultural fabric. Poor sanitation usually goes hand in hand with hunger and with inadequate education. A country that has a seeming rise in the rate of mental illness is also likely to have a complex physical and social environment. Hence, it is difficult to define health requirements in terms of specific organizational framework, precise program content, or per capita expenditures that would be comparable from one area to another.

Despite these and other variables, there are at least three principles of health planning and administration that we might consider. First, it is essential to determine the kinds of problems which organized health measures are designed to solve in any given country. Second, health, and patterns of public health administration, must be an integral part of the social, economic, and governmental structure of a community and a nation. Finally, many individuals and groups can contribute toward solving health problems, which means that sound planning must make a place for these contributions. Provision must be made within the organizations having health responsibilities—both governmental and nongovernmental—for an interchange of ideas and understandings and for working with numerous groups and agencies. Because of the complexity and the variety of needs, we must often go far outside the traditional public health setting to make effective progress.

Program Related to Needs

With this as background, I would define program planning as the mobilization of all resources and facilities to the best possible effect so that problems are solved. It seems to me that the last part of that statement is the most important. To talk about planning without relating it to the problems to be met is not only unrealistic, it is sterile. We are not planning for the sake of planning; we are planning for something. There must be an understanding of the problems to be solved, of the measures to be used in solving them, and of the objectives to be reached.

The next step is to undertake suitable courses of action for improving health and reducing the burden of disease. This step, of course, is never easy. A host of obstacles, real and fancied, organizational and administrative, may stand in the way. But an understanding of the problem will make any solution easier to arrive at. It will enable public health planners, for example, to look beyond a specific way of working or a particular kind of organization. Instead, they can evaluate what is available against what is needed and mobilize all of the resources which can be used to help meet the problem. Even in what to us might seem the most backward of countries, there exist many untapped resources and competencies which can be focused on health needs. If these resources are not used, many programs which look sound on paper may face insurmountable difficulties or, worse yet, may be doomed to early failure.

The Health Department's Job

What is the role, then, of the official health organization in a community or in a larger segment of government? First of all, it has a specific part of the total health job to do. This may vary all the way from providing certain direct services to setting standards or offering financial aid to other groups. In addition, however, the health department must recognize the underlying relationships of health measures and act as a general staff in coordinating all the community's health services. It should promote an integrated approach in order to achieve a common objective.

As was just noted, many obstacles stand in the way of effective program planning and execution. For example, programs are often launched without a real recognition of the problem or without relationship to the major needs. The demands of special groups, the dramatic appeal of certain diseases and conditions, the pressures of expediency, apathy and resistance to change may all throw sound planning out of balance. In addition, shortages of resources—funds, personnel, facilities—often prevent orderly program development. For this reason, a very careful estimation of the kinds and numbers of personnel and the amount of funds needed must be an essential part of program planning. For

this reason, too, a logical order of development must be worked out. In other words, we must set priorities which will allow us to expand or take on new responsibilities if the ingredients are available or to retreat in the event of shortages.

Balanced Program

This brings us to one of the biggest problems facing the underdeveloped countries: the balancing of immediate needs against long-term programs of permanent health service. First things must obviously come first. Because of the tremendous backlog of existing disease, many countries may turn to programs of medical care and hospital services. In doing so, however, they are often likely to neglect the preventive services and the public health organization through which these services can be brought to the people.

Both types of need must be met. In order for this to be done, the health organization must be flexible. It must be prepared to solve the pressing health problems and then move on to new programs without losing ground. We must always remember that we want to build dynamic organizations to meet dynamic situations. One of the ways in which this can be done has already been mentioned, that is, taking advantage of all health resources or all opportunities for improvement, no matter where they may be found.

In planning to take on new responsibilities, however, we must recognize the dangers inherent in piecemeal growth. Such a development is likely to foster an incomplete, segmented approach. Not only is an organization likely to grow unwieldy and difficult to administer but, more important, it may lose sight of total objectives. In program planning, we must always work toward a synthesis in order to direct our attention to the whole man and the whole community.

Trained Personnel

The caliber and kinds of personnel available play an important part in program planning and administration. Of particular importance is the need for auxiliary and nonprofessional

workers. Up to now little serious thought has been given to such personnel as inspectors, aides, technicians, and others who perform many of the routine operations in this country, and who could be relied upon to provide the bulk of services in less highly developed countries. As a result, even when program planning is relatively good, the actual conduct often falls below our expectations.

This must be considered an important element in sound planning for two reasons. First of all, the training of auxiliary workers should have a high priority in all organizations. Second, the organization should be such that maximum use is made of highly trained professional personnel. Routine details should be delegated to auxiliary or less highly specialized workers. I think we in this country have a great responsibility in learning how to use these workers more effectively and in helping other nations develop the kinds of personnel who will be suited to their needs.

Public Support

Public understanding and support can also be made a part of planning. Public health programs should be so organized that the people who have the problems are given an opportunity to plan and contribute to the solution. Too often there is little participation by the individual, who passively receives the services. In a sense, health officials should aim to make every citizen a public health worker, at least in his own behalf. This can be done, in part, by mass education combined with proper devices for motivation. In part, however, it depends on how soundly our programs are planned and how logically our organization is developed. I think there is no question but that people will support a program they can understand and that is meeting their real needs.

Public enlightenment becomes particularly important when planning health services in many parts of the world in which such services may be foreign or strange. We must remember that we have reached our present state of development in this country because health is part of our mores, is inextricably bound with our way of life. Personal hygiene and sanitation are taken for granted as part of our daily existence;

immunization and vaccination are accepted as necessary and desirable to preserve health.

In many parts of the world, however, such prerequisites do not exist. Some health measures may even go counter to local or national customs and may be fought by the very people they are intended to benefit. The importance, thus, of relating planning and organization to local needs, customs, and abilities cannot be overstressed. Although advisory and technical assistance may come from outside, lasting health reforms must be undertaken within a country and must be adapted to local conditions. Uniformity of methods and organization would be highly desirable, of course; but the wide diversities among different countries may dictate considerable variation in methods of achieving health goals. Many paths may be taken to reach the same destination.

Other Planning Needs

Other elements of sound program planning should be mentioned here, even in such a brief review. For example, we need to evaluate progress constantly and critically, in terms of our problems and goals, in order to overcome any tendencies toward self-perpetuation or toward allowing our work to become routinized. Other aspects of planning for health services

include such items as: the differentiation of functions at various levels in the governmental structure; the regionalization of health services; the necessity for alining preventive and curative medicine through the coordination of hospitals and health departments; the need for incorporating hygiene into industry, commerce, and public works; and the need for effective communication and for clear-cut lines of authority and responsibility.

I would conclude, however, with the need for increased exchange of experience and knowledge among all the countries of the world. Certainly, we in this country have as much to learn as we have to contribute to world-wide development. No single nation can lay claim to all the competence and all the wisdom. Moreover, public health programs everywhere—and certainly this country is as guilty as any other—are limited and rather narrow in scope. We have often failed to add new services to meet current health needs and to take advantage of new methodology to further the cause. We must thus raise our own sights as well as look toward the problems and needs of the rest of the globe. With a true spirit of cooperation, with a basic understanding of needs, and with the efforts of enlightened groups everywhere, we can push forward to new frontiers of world health and well-being.

To be solved Problems of Administrative Planning in World Health

- *How can the most pressing health problems in a given country be determined?*
- *What significance must be given to the mores of the people concerned?*
- *How can a balance be struck between programs designed to obtain immediate dramatic results and long-term programs to develop permanent health services?*
- *What per capita expenditure for health purposes is possible for a particular country?*
- *How may a program be planned so that it ultimately can be supported by local resources?*
- *What can the United States learn from the program-planning experience of other countries?*

The Need for Personnel

By GAYLORD W. ANDERSON, M.D., Dr.P.H.

Modern public health requires an adequate supply of well-trained personnel, whether the programs be conducted on a local or an international basis. Such a statement is almost axiomatic and should require no defense, yet experience shows that the truth of it is frequently not appreciated by those responsible for the planning and direction of public health. In too many instances there has been a virtual assumption that a reasonably adequate basic training in medicine, engineering, or nursing constitutes adequate background for the vast responsibilities of community health protection. Many of the failures and shortcomings of public health can be attributed to a lack of suitably qualified personnel.

Modern Concept of Public Health

This failure to appreciate the need for special training stems from the thinking of an earlier era when the prevailing concepts of disease were couched in terms of toxic emanations from decaying filth. Public health of that period was little more than a program of simple cleanliness and hence had no need of specially trained staff. While no one would question the accomplishments of such activities nor would doubt the potential benefits from their extension to many parts of the modern world, our present concepts of disease are not so delightfully simple.

Today we recognize the influence of a vast

Dr. Anderson is director of the School of Public Health, University of Minnesota, and president of the American Public Health Association. He conducted the sessions on professional health education at the Fourth World Health Assembly in Geneva last May.

array of physical, biological, social, and economic forces which operate either singly or in combination to exact a high toll of preventable illness and death. Modern public health is the synthesis of the contributions of a great variety of disciplines—a combination of the physical, natural, and social sciences, with a large component of the arts and the humanities. As such, it needs personnel with a sound foundation in their respective fields, supplemented by an understanding of the application of these disciplines to the prevention of disease and a broad appreciation of the interrelationships of the several fields of learning as they impinge upon public health.

A simple example will suffice to illustrate this need. The modern malaria control program is based upon the contributions of the physician, the parasitologist, the entomologist, the chemist, the toxicologist, the pharmacologist, the engineer, the nurse, and the educator. None of them can understand his or her role without some appreciation of the social, economic, political, and climatologic forces that condition the strangle hold that malaria has held on certain areas. Each must understand the relationship of his contribution to the total program for malaria control. Each must further realize that malaria control, like all other programs of public health, is a team operation in which each member must understand his particular function and its relationship to the tasks assigned to his associates. Unless this concept of teamwork is recognized, public health becomes a chaotic jumble of uncoordinated and, at times, conflicting programs, each of which is well-intentioned, but failing of its full potential contribution because it is not properly integrated with other closely related programs.

The training of personnel thus becomes one of the foundation stones of modern public

health. In the development of its world-wide program, the World Health Organization, following the example of several philanthropic foundations, has therefore very properly given major emphasis to training. A sizable fraction of its very limited budget has been set aside for this purpose. Some of it has been assigned to the betterment of training facilities within various countries. Another large part has been allocated to individual grants whereby selected personnel might be sent to appropriate centers for specialized professional education.

Varied Personnel Needs

The needs for personnel to be trained must obviously vary greatly from one country to another according to the culture and the problems of the respective nations. In the United States we speak glibly of the separation of curative and preventive services and toy with desired ratios between populations and the numbers of health officers, physicians, nurses, and sanitation personnel. Certainly there is no basis for assuming that such ratios have any meaning outside of our own area. In one country the most urgent need may be for more and better-trained physicians, for in that area there can be no fictitious separation of therapy and prevention. Another nation may have an acute shortage of nurses; in a third the sanitary engineer may be all but unknown, and a fourth may require physicians skilled in some medical specialty.

It would be highly unrealistic to pretend that any predetermined uniform standard might be used to describe the personnel needs of any country. We must recognize as a cardinal principle the fact that the needs of each country must be individually determined and that no agency such as WHO can ever do more than suggest to a nation the direction in which it should proceed in determining its training needs and allocating its training grants.

Personnel Selection

It would seem axiomatic, however, that in the selection of personnel to receive such grants, preference should be given to those who, upon return to their respective countries, will

be in a position to influence the development of sound programs and to contribute to the further training of their fellow countrymen. These persons must be sufficiently advanced in knowledge and experience so that they can profit from the stimulus of new contacts and ideas.

We must not expect, however, that all such students will be sent to one or two foreign countries well-equipped with training institutions. No nation can lay claim to a monopoly in public health knowledge, nor could the schools of any one country pretend to be able to furnish the detailed instruction requisite to meet all the health needs of areas of such different problems, customs, and culture. There is no suggestion that the health programs or procedures developed in one country are necessarily applicable to a distant land.

Those who are sent for foreign study must be persons with a background and understanding which will enable them to separate the basic principles from the operative details and select those ideas which are transferable to, or may be modified to meet, the problems of their respective countries. No greater error could be made either by student or teacher than to assume that the public health program of one nation could ever be transposed in its entirety to any other land.

Regional Training Centers

It would be equally fallacious to expect that every country, regardless of size, would ever be prepared to maintain full training facilities for all public health personnel. While most countries possess or can look forward to the establishment of schools of medicine, nursing, and engineering, there can be no justification for comparable development of schools of public health.

Rather we must envision regional centers serving nations of comparable culture and language, centers which will provide the basic training needed for those who are entering upon a career in public health. There can be little doubt of the waste of time and money when a person without a background of experience is sent to obtain basic public health training in a country whose language he does not under-

To be solved Recruitment and Training of Personnel for World Health

- *How can the training of additional personnel—particularly health officers, physicians, nurses, and engineers—be further facilitated, and to what extent?*
- *How far should training needs be met by the development of professional schools in areas where such facilities are now lacking?*
- *What responsibilities have universities and health departments in the United States for the temporary release of personnel for foreign service?*
- *What responsibilities has the United States for providing training facilities for foreign students?*
- *How far, and in what ways, can the limited supply of highly trained professional personnel be supplemented by the preparation of auxiliary workers—medical and nurses aides, midwives, sanitarians?*

stand. Such a student learns but little and, amidst the linguistic handicaps, finds himself unable to extract from the myriad details those few basic principles which, with suitable modification, he might apply in the position to which he will return. He becomes both confused and discouraged by the details which he recognizes as inapplicable to his country. Regional training centers, even if they lack some of the facilities of large foreign universities, would nonetheless serve a more fundamental need in the training of the great mass of personnel required for the public health programs of the various nations. Foreign study should be reserved for the advanced student.

Broad Training Programs

In planning for training programs, we must not forget that provision must be made for many types of personnel. I have already stressed the point that an effective public health program depends upon the contributions of persons of a wide diversity of professional backgrounds. If I may criticize our present training programs, I should say that we have given too little attention to nonmedical personnel. There has been too great a tendency on the part of schools of public health to overlook their responsibilities for the training of a coordinated team of workers.

We cannot leave the training of our co-workers to the mercy of professional schools having little or no real interest in public health. The modern school of public health should be a

place which receives professionally trained persons from a wide variety of disciplines and adds to their existing knowledge an understanding of the application of their specialities to public health problems and a grasp of the interrelationships existing between the contributions of each profession. The educational isolationism that has characterized so many of our professional schools is as unrealistic as was the political isolationism of an earlier generation.

Equally important in any training program is recognition of the needs of the subprofessional auxiliary worker. It must be quite obvious that the many tasks of public health do not uniformly require professional skills and that many countries will not possess within the foreseeable future an adequate supply of professional persons to perform the duties that one might wish to assign to them. It would be quite unrealistic to sit back and do nothing because of a shortage of persons of desirable professional background.

Many of the duties in environmental sanitation can be assigned to sanitarians lacking engineering background, and many of the instructional duties of the public health nurse may be carried out by a nursing aide, or home visitor. There are many situations in which the limited funds available for public health can be spent to best advantage in the employment of such personnel, provided they have had adequate training for the tasks to which they are to be assigned.

The problem of subprofessional training is simpler than that of professional education as it requires less time and expense. It should, however, be recognized as an important and fundamental part of a public health training program and not relegated to incompetent hands on the grounds that it is beneath the dignity of an academic institution.

Finally, may I stress the vital importance of the highest academic standards in any public health training program. It would seem unnecessary to point out that, dependent upon the various levels at which training is to be given, the academic standards should be the same as for other professions. Yet the personnel shortages are so great and the demand for personnel

so insistent that some have suggested lower standards as a means of attracting persons into public health work. Nothing could be more shortsighted, for the lowering of academic standards would automatically result in a deterioration in the professional quality of work and deter persons of real ability from seeking careers in public health.

What is needed today in all countries is an elevation of professional standards so that public health will attract the highest quality of personnel. Only in this way will we be able to provide personnel of the quality needed to carry on the manifold responsibilities of the program.

Meeting World Health Problems, 3

The Need for Public Understanding and Support

By A. W. DENT, LL.D.

Public health as the science and practice of preventing disease and infirmity through community efforts has developed slowly over the centuries, beginning first with quarantine laws as the barrier device to protect a well community from the invasion of epidemic disease carried by a sick person. Not very long ago some cities actually prohibited any newcomer from entering the gates until he had lived outside for a prescribed period, to prove that he was not sick nor likely to become sick.

Today such measures are impracticable. A well man exposed to a virulent form of influenza in New York could, traveling by air,

develop the infectious stage a few days later in India and conceivably continue on through Japan to San Francisco back to New York before being hospitalized, spreading the virus en route.

Moreover, mosquitoes, which carry many diseases, are unable to recognize quarantine. Some years ago the world's worst malaria vector, *Anopheles gambiae*, was found in Brazil, having been imported from Africa. It was eradicated from Brazil by the Rockefeller Foundation at a cost of millions of dollars. Dr. Raymond Fosdick has suggested that it might be cheaper to eradicate or control mosquitoes in populous areas of Africa than to rely on quarantine measures to prevent their introduction into new areas.

Obviously, public health programs need more than the enforcement of regulations to be successful: an educational effort is as necessary as the provision of safe drinking water or the sanitary protection of the food supply. People

Dr. Dent is president of Dillard University, New Orleans. He was a member of the United States delegation to the First World Health Assembly in 1948, and is now a member of the steering committee of the National Citizens Committee for the World Health Organization.

need an educational program which teaches the fundamental principles relating to protection of the health of themselves, their families, and their friends, and which will interest them in acting on this knowledge.

Development of Health Education

The first efforts in health education of the public might be described as the logical progression from the kind of language appearing on quarantine placards to a venture into the advertising field. Posters and pamphlets exhorted and ordered people not to do this or that and warned them against the horrors of various diseases. Health propaganda was the term used in those days and it is interesting to note that in many parts of the world today, particularly where there is much illiteracy, using graphic "propaganda for health" is still common practice.

But people do not like to follow orders blindly, and, this fact being noted by health educators, the next step was to take the public into closer confidence and explain the reasons for the orders, which now became recommendations. The principle that the major purpose of health education is to close the gap between scientific knowledge and its application in daily life was formalized. Obviously, if a sufficient degree of application of the knowledge of hygiene could be attained today by everyone, the public health millennium might be at hand. Unfortunately, however, there are many obstacles in the way: in the United States, movies, radio, television, automobile, hobbies, and the job of earning a living; in underdeveloped countries, illiteracy, religious practices and prejudices, the task of eking out an existence, and political unrest. The health educator must find means to overcome such obstacles, a task that can be done.

It is not enough, however, to make health knowledge available; the individual has to decide for himself to accept such knowledge and make it part of his way of life. As the physician, through the concept of psychosomatic medicine, has rediscovered the patient, so the public health worker has rediscovered the public he serves by the realization that people are best helped through understanding how to help themselves. So the third step in the develop-

ment of public health education is now being taken through the eminently practical concept of citizen partnership in the public health program.

The entry of the citizen as a participating partner in public health planning and action may have come about in the following way.

Public health programs cost money, and fairly early it became common practice for the health educator to explain the program to the public, point with pride to achievements, and view with alarm the unmet health needs of the community. He used his public as a channel for interpretation to all the people, and he harnessed the power of teams of volunteer workers as campaigners and contributors. But, finally admitted to the inner sanctum, the public has not chosen to leave.

The silent partner who provided the where-withal is becoming potentially a very vocal and intelligent participating partner, and on the farm, in the villages, the counties, and cities he is the flesh and bone of citizen health councils. Here is the newest tool to break through the shell of apathy. As more and more people join together to study their health needs and work out programs to meet these needs through community effort, they will be subject to the strongest incentives to make the application of health knowledge part of their way of life. To many health workers, helping to bring this about is one of the greatest challenges in the public health field today.

No, the goal of the modern health educator is not "to tell something to the people," nor is it "to work out a solution with the people." His objective is to help people to work out their own solutions to their health problems.

Citizen Participation in the World Community

Let us now turn to the wider scene—what local communities are doing, the world community can do. Ideally, what is needed is genuine citizen participation in the planning and work of the United Nations, participation by citizens of every country on the globe. I believe no one will disagree with this thought.

Here I wish to quote from a recent speech by Dr. Frank Boudreau, entitled "Our Stake in World Health," which he delivered at the an-

nual meeting of the American Public Health Association in San Francisco last October.

... Since its establishment the United Nations has been ceaselessly engaged in a desperate struggle to prevent the spread of war. Its attention has of necessity been concentrated on the prevention of aggression, the policing of the world. I realize that police forces are essential even in our most advanced cities. But peace is never a product of police forces alone. It is the fruit of mature minds in a healthy social and economic environment. I do not mean to decry the activities of the Security Council and the Assembly when I say that the real work of the United Nations is the organization of peace. Peace might be built, little by little, if men could be persuaded that the building of peace is just as important as the prevention of aggression. For police action may detect and punish the criminal, but rooting out the causes of crime is a task for other forces.

Economic and social development is needed to heal a sick world and set it on its feet. We have in the United Nations and the specialized agencies all the machinery needed for this purpose . . .

What are these specialized agencies of the United Nations to which Dr. Boudreau refers? There are 10 of them, including the United Nations Educational, Scientific, and Cultural Organization; the World Health Organization; the Food and Agriculture Organization; the International Labor Organization; the International Bank for Reconstruction and Development; and the Interim Commission of the International Trade Organization.

These are autonomous organizations with their own constitutions, legislative and executive bodies, budgets and secretariats, cooperating with the UN and with each other, and seeking to carry out chapter IX of the UN Charter calling for international action to promote economic and social progress. To their number should be added the United Nations International Children's Emergency Fund, an integral part of UN, which in its program cooperates with the specialized agencies.

We are all aware that public health is not an independent cause and that, to achieve better living conditions, people need to make progress simultaneously in several basic fields—in health, in education, in food production and nutrition, in transportation, in communication, and in the development of purchasing power. The Honorable Willard Thorp, Assistant Secretary of State for Economic Affairs, has remarked: "People who are sickly and weak

cannot produce efficiently and have little interest in learning. People who are poorly fed are more susceptible to disease and indifferent to education. People who are ignorant will not readily understand the reasons for sanitation and better farming practices."

Planting good seed and raising good stock are parts of the total program. WHO teams in India and Thailand have found that one of the best steps they can take is to get children to plant vegetable gardens. Engineers in Bengal found that with malaria under control the farmers in an area were able to produce 543 pounds more rice per acre. In many countries, building a system of good roads will raise the living standard more than any other single step. Trade can grow, labor can move about, food can be distributed. Dr. Winslow has reported that killing all the intestinal parasites flourishing inside the people on a Caribbean island would automatically double the food supply available to these people.

Citizen Councils

The work of the specialized agencies needs the understanding and support of citizens in all countries. The National Commission for UNESCO has led the way in the United States. At the Third World Health Assembly the delegates unanimously adopted a resolution urging the creation in their respective countries of citizen groups to build understanding and support for the work of the World Health Organization. Such groups have been formed in Finland, Austria, Japan, and Canada, and last October the National Health Council—the agency which is working with local and State health councils throughout the United States—announced the launching of a National Citizens Committee for the World Health Organization with the endorsement of the American Association for the United Nations—

... to increase through educational efforts public knowledge concerning the work of the World Health Organization, appreciation of the importance of international health programs, and understanding of the relation of public health issues involved to the general welfare of the world community. . .

These citizen groups should not be confused with the official agencies charged with the re-

- *What is the goal of public health education in world health programs—to tell something to the people, or to help them work out solutions to their problems?*
- *What may be learned by the United States from the programs of group thinking and mutual cooperation as applied by the WHO?*

sponsibility of cooperating with WHO in administering technical public health programs in their respective countries. The task of these groups is to cause people to appreciate their stake in world health as of immediate concern to themselves and their families and to involve them to the limits of their abilities in doing their share in raising the standard of health throughout the world. Potentially, this can be one of the most tremendous health education endeavors ever contemplated!

Therefore, let us in conclusion revise the title of this paper to "The Need for Public Under-

standing, Support, and Participation in Meeting World Health Problems." I have mentioned the National Citizens Committee for WHO. Here is an opportunity and responsibility for Americans to take up partnership in the work for world health. What should be the full purpose and activities of this committee? What should be its membership and how should it be organized? What should be its relationship with our governmental agencies, with WHO, and, in time, with similar citizen groups in other countries?

Meeting World Health Problems, 4

The Need for Money Resources

By FRANK G. BOUDREAU, M.D.

The task of answering the questions on the need for money resources should have been assigned to a hard-headed business man. Since I have accepted the assignment, however, I have no recourse except to do my best.

1. *How much money is now available for promoting the cause of world health?*

The draft budget of WHO reveals that in 1951 the regular budget was approximately 6.75 million dollars; in 1952, 7.9 million; and for

1953, the amount requested is 8.67 million. To these amounts should be added funds for technical assistance and the cost of needed supplies and equipment which must be imported. Grand totals would then be in 1951, 12.75 million dollars; in 1952, 22.33 million; and, in 1953, 24.33 million.

The Director-General of the World Health Organization points out that these amounts would not permit WHO to provide all the tech-

Dr. Boudreau, executive director of the Milbank Memorial Fund, was president of the League of Nations Association, 1939-44, and is now chairman of the steering committee of the National Citizens Committee for the World Health Organization.

nical assistance that governments have requested, and would fall far short of meeting the need for such assistance.

Other official and some voluntary international agencies expend funds on health activities. The United Nations Relief and Rehabilitation Agency set the example by expending 168 million dollars on health activities and the procurement of medical and sanitation supplies. The United Nations International Children's Emergency Fund is said to have spent or allocated about 162 million dollars in 5 years.

Funds for international health work are also provided by such national agencies as the Friends Service Committee, the Rockefeller Foundation, the Carnegie Corporation, the Commonwealth Fund, the Milbank Memorial Fund, and perhaps others.

Individual governments make outright contributions (in addition to their dues as members) or provide matching funds when they receive technical assistance.

We do not have anything like an accurate estimate of the amount of money now available for world health. For purposes of discussion I would guess—but it is a mere guess—that the total may reach 100 million dollars a year. However, we do know that far more funds are now available for world health than ever before.

WHO's present budget may be compared with that of the Health Organization of the League of Nations in its best year, plus the budgets of the Pan American Sanitary Bureau and the Office Internationale d'Hygiène Publique. These amounted to less than half a million a year.

2. *How much money could profitably be spent in the health field in the next 5 years, in view of limitations involved in program planning, available personnel, and receptiveness on the part of the people concerned?*

Let me deal first with these supposed limitations. Much more basic information for pro-

gram planning is available than is now being utilized. Intensive studies of malaria in India have been carried on for years. It would be an understatement to say that the information derived from these studies has not been fully utilized. The major health problem in underdeveloped countries is frequently an epidemic disease. Little time or energy is needed in planning for the prevention of such diseases. We need only to apply the knowledge we have.

Although even advanced countries need additional expert staff as is shown by the difficulty in filling high positions in the public health services, two things should be borne in mind: First, never in history have such large numbers of trained health officers been available; second, in underdeveloped countries wise use of trained staff, supplemented by large numbers of ordinary workers, will to a great extent overcome the deficiency. Methods and procedures necessary to prevent epidemic diseases are often simple enough to be learned in a few days by ordinary workers. Spraying with DDT, drainage and sanitation work, and immunization are examples.

Experience with the League of Nations has taught me that health administrations and universities are willing to allow members of their staffs leaves of absence for 1 month to 2 years for work in foreign countries under the auspices of an accredited international agency. Programs of social and economic development, including health programs, must as a rule be carried out by the people of the country concerned. Foreigners cannot assume responsibility because of their ignorance of the language, customs, and psychology of the people, but experts can help train local workers and aid in planning and supervision.

The lack of receptiveness on the part of the people concerned is not always difficult to overcome. If a foreigner tries to modify the way of life of an illiterate native, he may fail. But surely the foreign expert will work through the people of the country concerned—the individuals who must in the long run be responsible for carrying out the program.

Natives without formal education may be far more receptive to educational programs than is generally believed. One season's antimalarial, anti-kala-azar work by a WHO team

in a rural district of Pakistan cost about 17 cents per capita. It was effective in increasing the rice crop yield and in reducing sickness and death rates. A canvass of 360 families in the district showed that 80 percent of the family heads were willing to contribute about 11 cents per head per year for the continuation of the work.

I now come to the main question. How much money could profitably be spent in this field in the next 5 years?

Believing that the best way to spend funds for world health is to place such funds at the disposal of WHO I restrict my answer to expenditures of that organization.

My guess would be that a minimum of a billion and a half dollars could be spent usefully by WHO and its regional bureaus in the next 5 years. I exclude from this figure capital expenditures for waterworks, filter plants, drainage schemes, and other similar items.

Increasing fractions of this total could be used to good advantage as experience and maturity are gained.

3. *Should funds for health personnel, the training of personnel, and the provision of materials (such as DDT and penicillin) be supplemented by capital funds for permanent investment in such enterprises as waterworks and drainage schemes?*

This brings up the problem of short-range versus long-range programs. An anti-epidemic campaign which is not followed up may do more harm than good. But peoples who bear the burden of malaria, smallpox, dysentery, cholera, typhus and typhoid fevers long to be free of these scourges. The first step in a long-range program may well be a sharp anti-epidemic campaign to reduce sickness, deaths, and the economic waste due to unemployment because of disability, as well as heavy costs of medical treatment and funerals.

Such short-term programs must be steps in long-range plans for economic and social development, and these will require capital funds for permanent investment in drainage schemes, water supplies, and power development.

4. *Through what agencies can funds for public health best be spent (WHO, the technical assistance programs, etc., or through direct bilateral agreements between countries)?*

The growing desire on the part of the more advanced peoples to help their neighbors is one of the most heartening trends of our time. The desire is manifested by action through international and national, official and voluntary agencies. The present need is so great that all funds, from whatever source, can be used to good advantage. On the one hand, the value of pioneering explorations and demonstrations by private agencies, which often open the way for official action, must not be overlooked. On the other hand, comprehensive plans for economic and social development, including health, can be carried out most effectively by the UN and the specialized agencies.

WHO is a partnership. Members have equal status and an equal voice in decisions. The member country receiving aid has a vote; its point of view is represented; there is no feeling of an inferior people receiving charity from a rich neighbor. Just as important is the fact that WHO speaks for the world and is concerned with world health.

WHO has the very considerable advantage of being able to bring a variety of experience to bear on the health problems of any country. Experience in a highly industrialized nation may not be of the greatest value in one just emerging from primitive conditions. The experience of a nation which has recently emerged from this state may teach more useful and more readily applicable lessons. All varieties and stages of experience are represented.

On the other hand, I believe that the method of bilateral agreements has the greatest disadvantages, for the history of these is linked with empire building and the creation of political spheres of influence. A country which offers to help another is suspected of having other than purely altruistic motives. Moreover the receiving country may not feel free to differ with its philanthropic neighbor, to express its own views, to maintain national policies which, however reasonable, may offend the government from which it receives aid. It may feel it is not a free partner in a joint enterprise. It is a natural, but in my view, a mistaken policy to tie up technical assistance with political advantages, no matter how reasonable and sound.

I have already pointed out that assistance through a bilateral arrangement lacks that

variety of experience which is found in an international agency and may therefore be less suitable and less effective.

It must never be forgotten that technical development may bring disaster if it is partial or one-sided. Campaigns to prevent epidemics may succeed, but if nothing is done to promote political, social, and economic development, the final result may be that larger numbers of people live in greater misery. Or if the only attempt is to provide greater supplies of raw material to be processed elsewhere, the people of the region will not be helped but hindered. There must be advance on all fronts. This requires the formulation and carrying out of comprehensive plans embracing all important aspects of development.

The United Nations and the specialized agencies include the most important social and economic fields of work. This international machinery was built for the purpose of promoting social and economic progress in underdeveloped regions. It is to these agencies that we must turn for planning, general direction, and supervision of the entire program.

5. *What should be the share of the United States of America in financing world health?*

The World Health Organization has decided that not over one-third of its direct budget should come from any one country (but indirect grants for technical assistance, which may be assigned to WHO, and grants to its regional offices are not limited).

If, as I believe, an important principle of the foreign policy of the United States is that peace and prosperity will be brought closer by helping underdeveloped countries and regions to help themselves, then the United States contribution to WHO should be based upon what we believe WHO is capable of achieving in spearheading the movement for comprehensive social and economic development. In deciding on the size of its contribution the Government should take into account:

That health is the least controversial subject for international cooperation, since it involves no element of competition. More health in Asia means not less but more health in other countries as well.

That international cooperation in health matters has had a highly successful record.

That modern methods permit rapid control of many of the epidemic diseases which impoverish countries and from which the peoples of such countries long to be delivered.

That preventable illness and premature deaths often have disastrous effects on the economy of a region as well as on the psychology of the people.

That in the field of health, men of different races and creeds work easily together for objectives in which all men believe and which are of benefit to all.

To be solved Assembly and Allocation of Funds for World Health

- *How much money could profitably be spent in this field during the next 5 years, in view of limitations involved in program planning, available personnel, and receptiveness on the part of the people concerned?*
- *Should funds for health personnel, the training of personnel, and provision of materials be supplemented by capital funds for permanent investment in such enterprises as water-works, drainage schemes, hospitals, and the like?*

- *What should be the share of the United States in financing world health activities?*

International Technical Assistance in Public Health

a portfolio of maps and pictures

FAMINE, ignorance, disease have been endured for centuries by great numbers of people in many parts of the world.

During recent decades—especially since World War II—there has been a growing awareness that improvement is both possible and imperative for the benefit of the entire world community. The idea of Point IV—the neighborly sharing of techniques and resources—epitomizes the new outlook and finds practical expression in a variety of international technical assistance efforts.

In this portfolio, *Public Health Reports* sketches the scope and character of the health assistance programs, bilateral and multilateral.

The Objectives of the United States

1947 "The purposes are to further the general welfare of, and to strengthen friendship and understanding among, the peoples of the American Republics through collaboration with other governments . . . in planning, initiating, assisting, financing, administering, and executing technical programs and projects, especially in the fields of public health, sanitation, agriculture, and education."

—from section 2 of Public Law 369, 80th Congress, creating the Institute of Inter-American Affairs

1948 "It is declared to be the policy of the people of the United States to encourage these countries through a joint organization to exert sustained common efforts . . . which will speedily achieve that economic cooperation in Europe which is essential for lasting peace and prosperity. . . . To sustain and strengthen principles of individual liberty, free institutions, and genuine independence . . . through assistance to those countries which participate in a joint recovery program based upon self-help and mutual cooperation."

—from section 102 of Public Law 472, 80th Congress, creating the Economic Cooperation Administration

1950 "The peoples of the United States and other nations have a common interest in the freedom and in the economic and social progress of all peoples. Such progress can further secure the growth of democratic ways of life, the expansion of mutually beneficial commerce, the development of internal understanding and good-will, and the maintenance of world peace.

"It is declared to be the policy of the United States to aid in the efforts of the peoples of economically underdeveloped areas to develop their resources and improve their working and living conditions by encouraging the exchange of technical knowledge and skills and the flow of investment capital to countries which provide conditions under which such technical assistance and capital can effectively and constructively contribute to raising standards of living, creating new sources of wealth, increasing productivity, and expanding purchasing power."

—from sections 402 and 403 of Public Law 535, 81st Congress, establishing the Technical Cooperation Administration to carry out the objectives of the Point IV program

1951 "The Congress declares it to be the purpose of this Act to maintain the security and to promote the foreign policy of the United States by authorizing military, economic, and technical assistance to friendly countries to strengthen the mutual security and individual and collective defenses of the free world, to develop their resources in the interest of their security and independence and the national interest of the United States, and to facilitate the effective participation of those countries in the United Nations system for collective security."

—from section 2 of Public Law 165, 82d Congress, establishing the Mutual Security Agency and carrying forward the economic and technical cooperation programs

The Multilateral Approach

Through the United Nations the concept of international health has found its most potent means of expression. The multilateral approach to public health—in which the resources of many nations are mobilized for the common good—is found in the programs of the specialized and other organs of the United Nations. Among these are the International Labor Organization (ILO), the Food and Agriculture Organization (FAO), and the United Nations Educational, Scientific, and Cultural Organization (UNESCO). There are two agencies directly concerned with health: The World Health Organization (WHO) and the United Nations International Children's Emergency Fund (UNICEF).

. . .

Aiming at "the attainment by all the peoples of the highest possible level of health," WHO acts as the

international health coordinating authority; assists governments, upon request, in strengthening health services; furnishes technical assistance and, in emergencies, aid upon the request or acceptance of governments; stimulates the eradication of epidemic and other diseases; promotes maternal and child health and welfare; fosters activities in the field of mental health; and maintains administrative and technical services, including epidemiological and statistical services.

. . .

The United Nations International Children's Emergency Fund is an international cooperative on behalf of children. It draws upon those nations able to help with money, goods, and services and distributes aid to countries on the basis of children's needs which cannot be met from the countries' own resources. In doing

so, it works with and through governments, the latter carrying the full responsibility for administration. The United States participates in UNICEF.

UNICEF provides assistance to countries for general maternal and child welfare purposes, including the building of basic services, training of child welfare personnel, mass campaigns against diseases that particularly affect large numbers of children, milk conservation projects, and in the meeting of emergency situations of special groups in particular need.

Other intergovernmental organizations which are concerned with health activities are: Pan American Sanitary Bureau, the Caribbean Commission, the South Pacific Commission, the Colombo Plan for Co-operative Economic Development in South and Southeast Asia, and the Commission for Technical Cooperation in Africa South of the Sahara.

The Bilateral Approach

The United States—having emerged from World War II with its economic position stronger than other countries and in a position of international public trust—has made significant contributions of funds and technical assistance to other countries to aid in economic recovery and establishment of greater stability throughout the world.

This nation actively participated in the creation of the World Health Organization as a specialized agency of the United Nations. By Congressional resolution, approved by the President on June 14, 1948, the United States became a member. Through the WHO we substantially contribute to its multilateral programs. And in carrying out bilateral programs, the United States looks constantly to the WHO for leadership and guidance, recognizing the coordinating authority given in its constitution, to which this Nation is a party.

United States experience with the bilateral approach—a direct arrangement between two nations—had its first trials in the health field during the last war through the Office of the Coordinator of Inter-American Affairs. In 1940, came the Philippine Rehabilitation Act. The Eightieth Congress created the Institute of Inter-American Affairs (IIAA) and in the Foreign Assistance Act of 1948 established the Economic Cooperation Administration (ECA)—instituting a far-reaching program with a direct and immediate impact on health conditions. The Act for International Development in 1950 set up the Technical Cooperation Administration (TCA) in the Department of State to develop the Point IV program. The Mutual Security Act of 1951 carries forward the economic and technical cooperation activities of this country.

United States technical assistance appropriations for the fiscal year

1952 are in the range of 400 million dollars, about 10 percent being applied to bilateral technical assistance in health. Programs aimed at strengthening national and local health services are now operating or under development in 41 countries upon requests of governments.

. . .

The bilateral health assistance programs of the United States are coordinated under the general supervision of the Director of Mutual Security in the Executive Office of the President. The two major operating agencies are the Mutual Security Agency (MSA—successor to the Economic Cooperation Administration) and the Technical Cooperation Administration. The Institute of Inter-American Affairs is a functional part of TCA. The Public Health Service of the Federal Security Agency supplies technical support and much of the health personnel for both programs.

Europe

Technical Assistance in Public Health

MANY countries of Europe have health problems which affect their national economic development. For this reason, the World Health Organization, during its last assembly, decided to establish a regional office for Europe. Because of the advanced development of health affairs in Europe, the United States is giving technical assistance to only two countries—Greece and Turkey—in a bilateral program.

The present Greek program was initiated in 1947 as a part of the American Mission for Aid to Greece. It was designed to help in the economic recovery of Greece by controlling those diseases which affect the health of workers or make areas of the country unsuitable for agricultural production. Consequently, malaria control was one of the biggest tasks when the program began. This program was carried out on a large scale by the public health division and the agricultural division of the Economic Cooperation Administration (ECA) mission to Greece. Once a major health and economic problem, malaria is now reduced to a minor problem in Greece.

The ECA—now Mutual Security Administration—mission to Greece is now providing advisory services to the Greek Ministry of Hygiene in helping to reorganize its structure and to plan public health programs which will extend into the provinces. In addition to developing health centers in the provinces, the mission is building hospitals, promoting nursing education programs, developing hundreds of community water supplies, and supervising the procurement and distribution of medical stores, drugs, and chemicals. Together with WHO, the Greek Government, and the Danish Red Cross, the mission is also operating a tuberculosis control and BCG vaccination program.

In Turkey, a small United States mission, comprising four persons, is giving assistance in malaria control. The activities of the mission are centered in those regions where rice production was stopped by the Turkish Government because of an increase in malaria. This

team also serves the Government in a general advisory capacity on other health problems.

Because of the high degree of development in the field of health in Europe, the WHO has very few technical assistance missions such as those assigned to the underdeveloped countries. Such assistance as is being given is confined to short-term seminars and demonstrations. WHO, along with the United Nations International Children's Emergency Fund, however, has been instrumental in initiating extensive BCG vaccination programs in the war-ravaged areas of central and eastern Europe.

An international antivenereal disease commission of the Rhine was created in 1951 to coordinate services of the five countries bordering on the river and to establish diagnostic and treatment centers at principal river ports.

A training center for anesthesiology, opened in Copenhagen in May 1950, is being operated by the Danish State Medical Board, the University of Copenhagen, and the WHO. Training in new techniques is being given to specialists from Sweden, Norway, Finland, Iceland, Yugoslavia, and Austria, as well as from Denmark. The first class was graduated in 1951.

A WHO team of six Swedish heart specialists demonstrated new surgical procedures, such as "blue baby" operations, in Vienna and Zagreb. Following the team's visits, cardiac clinics for children were scheduled to be established.

Two school children follow the example of the AMAG poster which encourages children to drink milk.

Student nurses train in ECA-constructed schools under supervision of public health teams.

A new wing is added to this hospital as part of the general construction plan.

When AMAG arrived conditions such as this were common. As many as 14 people lived in these two floorless 1-room huts.

Hospitals, Nurses for Greece

At the end of World War II, many of the countries in Europe were left with hospitals and schools torn and damaged. In Greece, especially, the need for adequate medical facilities was great, for the country became involved in a civil war shortly after World War II. In 1947, the United States assigned the American Mission for Aid to Greece (AMAG) to provide technical and financial assistance requested by the Greek Government, and in July 1948, ECA was assigned to take over and further the work of AMAG and to aid in the establishment and operation of a health program for Greece.

The agreement between the United States and Greece included projects for the training of Greek nurses, and for the construction and improvement of hospitals, sanatoriums, and nursing schools in Greece. By mid-1951, five new buildings were in use: two public health centers; a tuberculosis sanatorium at Sparte; a medical supply warehouse at Athens; and the Greek Red Cross Nurses' School in Athens. It is expected that two new schools of nursing will be opened during the present year, one at Salonica and a school for practical nurses at Laikon Hospital, Athens.

The additional nursing facilities resulting from the construction of nurses' homes have been responsible for an increase in the number of women entering the field of nursing. The number of nursing students increased about two and one-half times in the period from 1945 to 1951.

As a result of the high standards introduced into the field of nursing by the ECA public health mission, greater recognition is being given to graduate nurses, hospitals are placing graduate nurses on their staffs, and the number of graduate nurses has been increasing, until, by the middle of 1951, there were 891 graduate nurses in the country.

Close-up of latrine excavation operations.

One of the new latrine shelters.

Sanitation Primary Aim in Iran

A major problem in the Middle East is that of providing an adequate and safe water supply for the population. Coupled with this is the need for sanitary disposal facilities. In Iran, this problem is receiving the attention of the public health division of the Technical Cooperation Administration.

Under the direction of American sanitary engineers and their Iranian counterparts, sanitation projects, providing safe water supplies and waste disposal facilities, are in operation. These projects are part of a general rural improvement program which is raising the living and health standards of the population. Eventually the entire program will be completely staffed and operated by Iranians.

The location of the first sanitation project was in the village of Kamalabad, about 37 miles northwest of Teheran. In this village of 500 population, a well was drilled at the school and a sanitary latrine constructed. At present, a public bath is nearing completion.

One of the primary aims of the sanitation program is to increase the number of individual and community latrines. Latrine tops adapted to the mores of the people are being manufactured in Teheran for TCA and distributed to those villages which agree to install and maintain them according to direction. These latrine tops

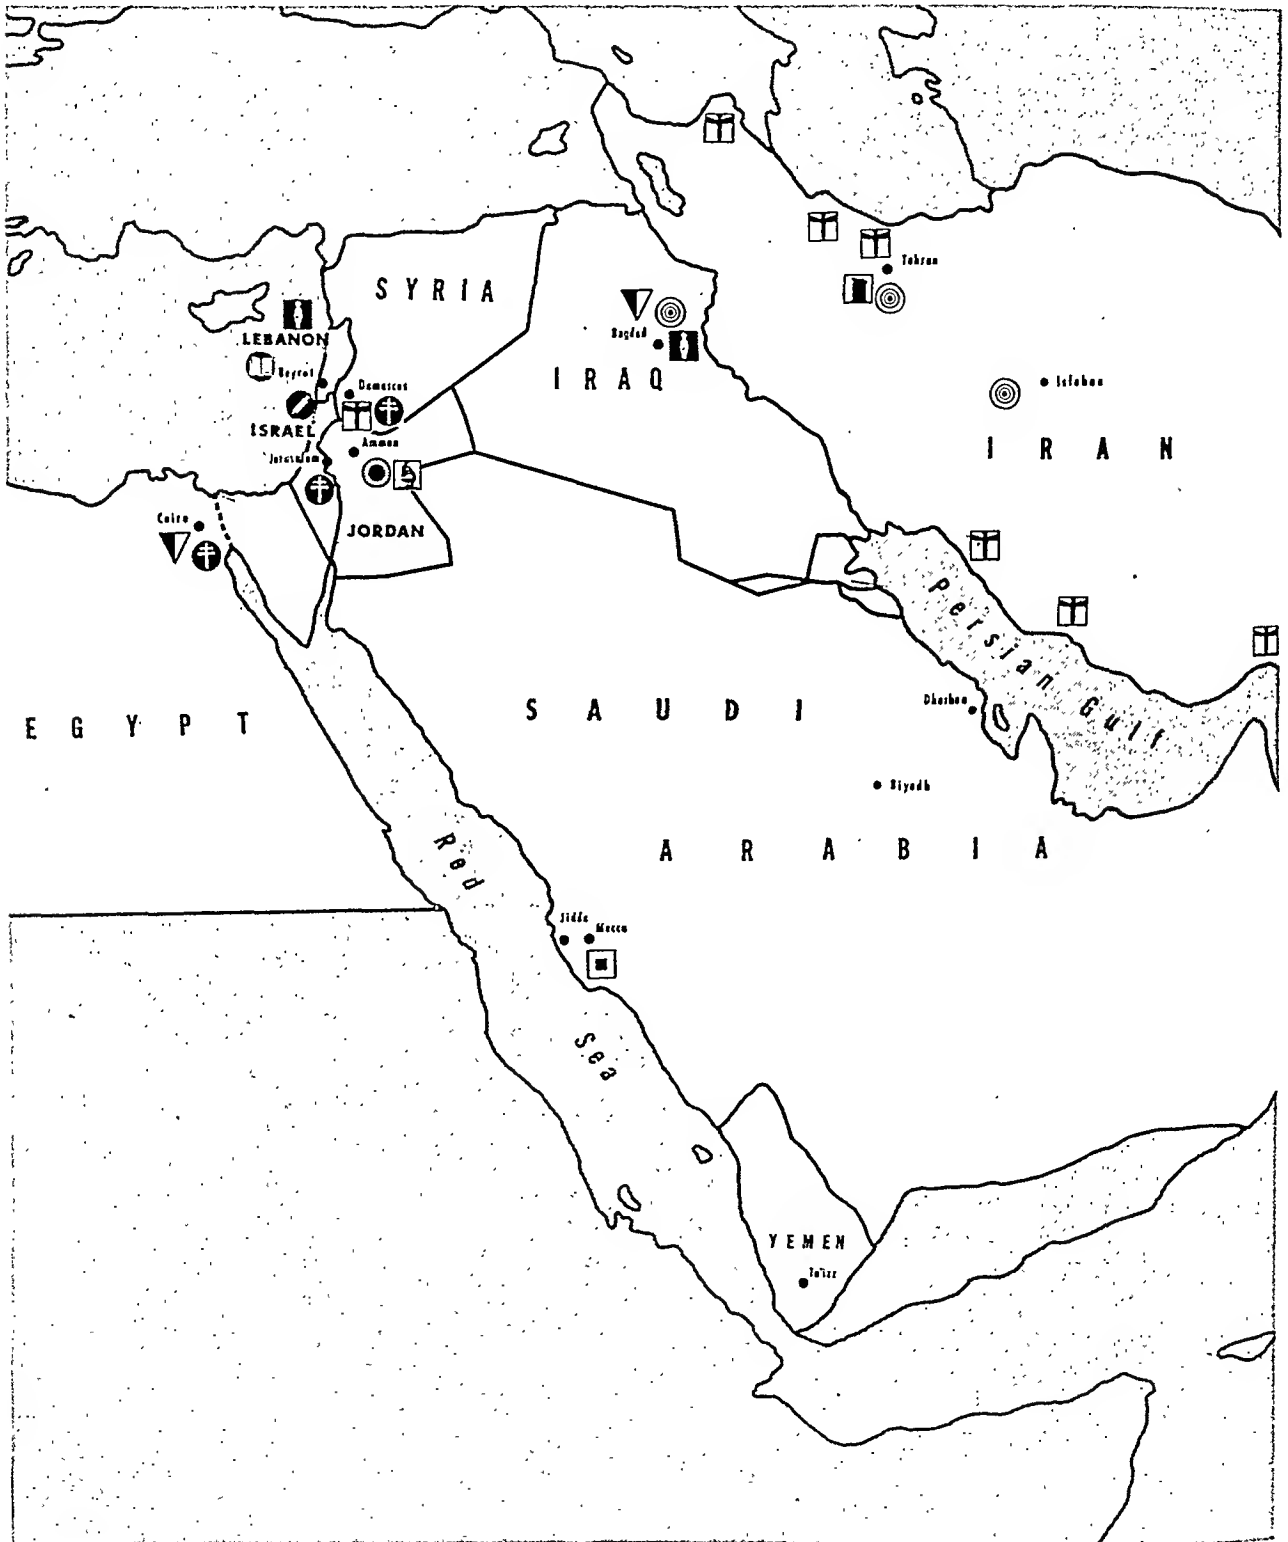

have been built with colorful mosaic tops, with the expectation that their decorative appearance will provide an additional incentive for cleanliness in maintenance.

Because of the great need for safe water in Iran, it is considered essential that water supply facilities be constructed before additional health work is begun. Therefore, plans for the future include the drilling and equipping of 500 deep wells in 1952, and the development of an additional 1,500 wells in the following 3 years.

Well-drilling operations in Ali Shah Avez.

Middle East

Technical Assistance in Public Health

BORDERING the southeastern shores of the Mediterranean Sea and extending south to the Sahara Desert and east to the Caspian Sea and the Persian Gulf is an area of the world often referred to as the Middle East.

A major problem of this area is the movement of population—refugees, immigrants, and pilgrims. There are hundreds of thousands of homeless Palestine refugees temporarily settled in Lebanon, Syria, and Jordan. Immigrants continue to flow into Israel. Every year, 200,000 Moslems make their pilgrimages to Mecca in Saudi Arabia. These movements have far-reaching political, social, and economic importance, including their effect on disease transmission.

These are among the reasons the United States and the United Nations agencies are channeling much of their technical assistance to the countries in this area. The United Nations International Children's Emergency Fund and the World Health Organization are supplying medical personnel and supplies to stave off epidemics among refugees. One hundred and forty-eight thousand refugee children have been vaccinated against tuberculosis. Control programs against malaria, typhus, and other insect-borne diseases are carried on by these international organizations in the refugee camps.

Infectious eye diseases, such as trachoma, are being attacked in Jordan. With United States equipment and technical direction the Government of Jordan has set up a central laboratory to provide essential laboratory services required in attacking the problems of communicable diseases in that country.

The Saudi Arabian Government, with WHO assistance, has built quarantine facilities at Jidda to control diseases among the pilgrims.

UNICEF and WHO are sponsoring vaccination programs throughout the area for protection against tuberculosis. In Israel, 208,000 children have been vaccinated, while in Egypt some two million children and young adults have been tested. A vaccine production

center is being established in Cairo with the assistance of WHO and UNICEF.

The Maternal and Child Health Center in Beirut is training local maternal and child health teams for work in the rural villages. The United States Technical Cooperation Administration has helped to set up training facilities at the American University of Beirut for subprofessional and professional public health workers from all the nations in this area.

WHO and UNICEF also bring medical care to thousands of men and women in Iraq suffering from bejel, syphilis, and other spirochetal diseases. TCA is establishing rural public health demonstrations in areas of Iraq undergoing economic development.

For the first time, the rural population of Iran is receiving the benefits of public health, scientific agriculture, and fundamental education. In each of the provinces, or ostans, a team of technical experts is setting up regional health centers as part of the TCA program. These centers are serving as focal points for training subprofessional health workers. Also, TCA and WHO, in cooperation with the Ministry of Health, are very rapidly bringing malaria under control in Iran.

Africa

Technical Assistance in Public Health

AFRICA, the second largest continent of the world, has only 15.1 people per square mile, compared with North America's 22.1, Asia's 72.6, and Europe's 142.0. In the central part of the continent is a region many times greater in area than either the pampas regions of South America or the prairies of the United States, which is rich in natural resources. But much of it at present is virtually uninhabitable. If made safe for human habitation, this region could supply much of the needed food for the world.

Most of the diseases known to man are found in Africa. Particularly prevalent are malaria and African sleeping sickness. Smallpox, typhus, epidemic meningitis, yellow fever, hookworm disease, and malnutrition are also widespread. In some of the drier areas of the continent, trachoma, a disease often causing blindness, strikes as many as two out of every three inhabitants. Along the coast, syphilis and gonorrhea have invaded the towns and villages. In the interior, yaws incapacitates both children and adults.

The prevalence of these diseases not only hinders the development of Africa, but also presents possible threats to health in other areas of the world, since many of the diseases may be, and have been known to be, transported to other countries. Man has discovered methods for the control of most of the diseases, but the economic cost of applying such measures on a large scale remains a formidable barrier.

The United States is presently giving technical assistance on health problems to two countries in Africa—Liberia and Ethiopia—under a bilateral program.

In Liberia, the bilateral program has been in operation since 1944. Originally initiated as a wartime operation to protect American military personnel stationed in that country, the program is now an integrated part of the public health services of Liberia. The American staff of the mission is assigned to responsible positions in the national health service. Ameri-

can experts provide assistance in nursing education, malaria control, and laboratory services, as well as in rural sanitation and other types of health services. At the request of the Liberian Government, the World Health Organization has provided a consultant to draft and codify health regulations. WHO is also providing personnel to undertake a yaws control program in that country.

WHO has been providing assistance to Ethiopia for several years. Due to the extreme shortage of trained personnel in the health fields, the program has been restricted primarily to the training of subprofessional personnel. Recently, however, the country has received assistance from WHO in leprosy control, and a project for the control of venereal disease has been approved. The Technical Cooperation Administration has approved the assignment of a public health administrator to Ethiopia to plan a national health service for that country. It is anticipated that additional personnel will be assigned to Ethiopia when a plan has been agreed upon.

Other important health activities in this region include a malaria survey in Sierra Leone and epidemiological studies in the Gold Coast and Nigeria, which have been sponsored by the Mutual Security Agency.

WHO has recently established a regional office for Africa at Brazzaville, French Equatorial Africa.

A class at the Tubman School of Nursing.

Midwives receive instruction in prenatal care.

Native midwife plans new nursing home.

Liberia Trains Midwives and Nurses

Midwifery in Liberia, as in many countries in the world, is an important phase of the health program since virtually all Liberian babies are delivered by midwives. The United States Public Health Service Mission in the capital city of Monrovia, which was established in 1944 at the request of the Liberian Government, almost immediately began elementary training for midwives. Classes filled up quickly at the mission and other classes were started in nearby villages in response to eager demands.

After learning improved techniques in midwifery, the tribal midwives return to their own villages, where they use their new skills in delivering babies either in their own homes or in special places prepared for this purpose.

One of the midwives, from the Bassa tribe, who has been working in the clinics of the Public Health Service Mission in Monrovia for the past 2 years, is hoping to open a small nursing home in her village, where she may take her patients for deliveries. At present she is using her own home. She plans to christen her new nursing home "SMALL USPHS" in appreciation for the training and other help she has received from the mission. Among her people, she is considered a "big woman" and her influence has been strengthened by the guidance she has received at the mission.

A major milestone in the training of midwives was the opening of a 2½-year course in midwifery at the Tubman School of Nursing in Monrovia in March 1951. This course offers training in the basic principles of prenatal and postnatal care, newer and improved delivery techniques, and patient and infant care. Nineteen students are presently enrolled in the course.

The Tubman School of Nursing, a cooperative project of the United States and Liberia, was established in 1946 to help solve Liberia's problem of providing professionally trained health people. The school offers a training program which meets nurse training standards in the United States and other countries. Its 23 graduates to date (1948-51) are now serving as clinical and public health nurses in various parts of Liberia.

Patients registering prior to examination—part of the venereal disease control program.

Penicillin Comes to India

In the early months of 1949, at the request of the Government of India, the World Health Organization established a venereal disease demonstration team in the Himachal Pradesh, the foothills of the Himalayas. In this area, which has a population of about one million, the problem of syphilis was severe. The team, consisting of a physician, serologist, public health nurse, and health educator, had its headquarters at Simla, the largest city in the area.

Shortly after the arrival of the first member of the WHO team, the Indian matching-team leader was assigned. The existing laboratory at Simla was found to be adequate for the clinical work and testing that was necessary, and work was begun there. The team was quite successful in introducing penicillin therapy to the region. Local physicians and hospitals quickly accepted this method, as well as team-demonstrated techniques for serologic tests for syphilis.

The primary function of the venereal disease control team was the training of local doctors and other health personnel who could continue the work after the team's departure. In the first 17 months of activity, 29 persons had completed training under direction of the team. These trainees, in turn, have assisted in the training of additional health personnel, and have initiated venereal disease control measures in the various hospitals and clinics in India. The success of the team in this phase of their work indicates that a program begun with outside assistance and direction can be absorbed into the provincial health services of a country.

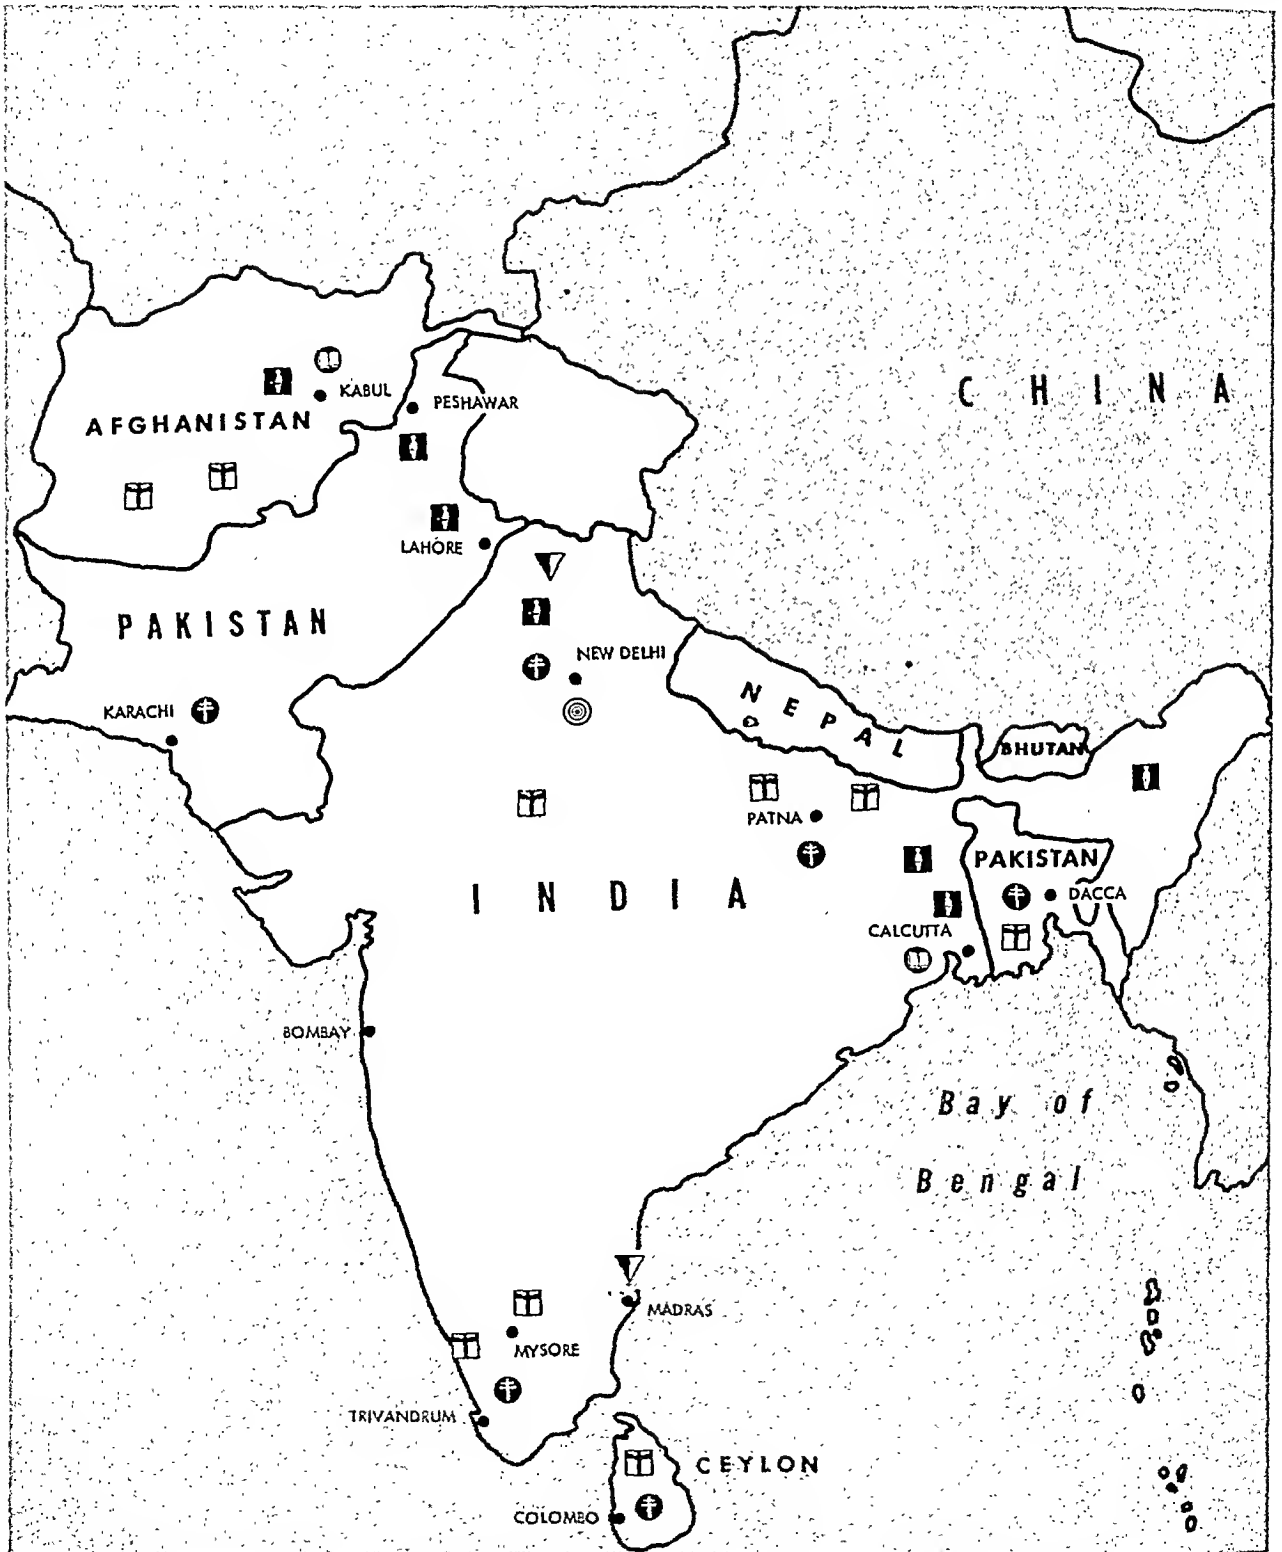

A venereal disease control team preparing for a trip into the Ghund region.

South Asia

Technical Assistance in Public Health

MORE than 400,000,000 people inhabit that area of South Asia politically divided into the states of Afghanistan, Pakistan, India, Nepal, and Ceylon. These people are of many races, religions, and castes. Equally varied are the topographic and climatic conditions, ranging from the intense cold of the Himalayan Mountains in northern India and the barren plateaus of Afghanistan to the humid tropical lowlands of Ceylon. All of these people have one thing in common—untold human suffering resulting from ill health and undernourishment. The limited fertility of the soil and the rapid population growth present serious obstacles to the social and economic development. Many of the resources of the United Nations organizations are devoted to this area. Also, the United States has allotted considerable funds for technical assistance to these countries. The Technical Cooperation Administration has assigned a public health administrator to India to assist in developing specific projects for countries in this area.

The United Nations organizations have been operating in this area for several years and have a number of programs under way. In Afghanistan, the World Health Organization and the United Nations International Children's Emergency Fund have combined to establish basic maternal and child health services and training facilities for nurses and midwives. During the past year, the WHO assisted the Government of Afghanistan with two malaria control demonstrations, reducing the infection rate among children in the controlled areas by over 50 percent.

After 2 years of work in Simla, India, during which time 40 local venereal disease teams were trained, the WHO venereal disease control team has been assigned to the Madras area to set up a similar clinic and laboratory training center.

Jointly with the Food and Agriculture Organization, WHO has operated malaria control projects in four districts of India (Uttar Pra-

desh, Orissa, Mysore, and Malabar) and has trained 100 local teams to carry on malaria control activities.

Tuberculosis training centers have been opened in Delhi, Patna, and Trivandrum, and more than 4,000,000 Indian children have been tuberculin tested. WHO and UNICEF are assisting the Government of India in developing, in Calcutta, a maternal and child health center as part of the All-India Institute. This center will provide subprofessional and professional undergraduate and graduate training in preventive medicine, obstetrics, and pediatrics. From those who have completed this training will come the personnel to be used in expanding the 100 maternal and child health centers and the three pediatrics training centers which have already been set up in India.

In order to expand and strengthen the 100 maternal and child health centers in Pakistan, WHO and UNICEF have established five maternal and child health training centers for midwives and nurses and have provided the technical staff, supplies, and equipment for the centers in Lahore, Karachi, and Peshawar. The malaria control demonstration work in East Pakistan, which reached 250,000 persons, is being expanded to reach 1,000,000 people. A nation-wide BCG program centered at Karachi and Dacca, is being undertaken.

The WHO/UNICEF program in Ceylon has focused on malaria control and tuberculosis vaccination. The DDT residual spraying program, started several years ago by the Ceylonese Government, has been very effective.

Southeast Asia

SOUTHEAST ASIA is probably the most complex of the regions which are receiving technical assistance in health. This peninsular region extends from the under side of China to thousands of small islands known as the East Indies and the Philippines. Eight independent nations—Burma, Thailand, Viet-Nam, Cambodia, Laos, Formosa, Indonesia, the Philippines—one dominion, Malaya, and a number of non-self-governing territories occupy this area.

The United States is devoting intensive efforts to relieve the suffering of the people in this area and to assist the governments to develop sound economies which can include sup-

port for adequate health services.

In Indochina, where the French and Viet-Nam Governments are still fighting Communist rebels, relief and care for civilian casualties and war refugees necessarily constitute a considerable part of the health program. Fifteen American experts supervise malaria control teams, operate trachoma clinics, direct the drilling of wells and the building of privies in the villages, train and supervise first-aid workers, laboratory technicians, dressers, and other subprofessional personnel, and provide the technical guidance for the construction and equipping of hospitals.

Technical Assistance in Public Health

In Thailand, American experts are assisting the Ministry of Health in venereal disease, malaria, trachoma, and plague control programs, rural sanitation, and professional education. WHO and UNICEF have initiated a 3-year yaws control program and are assisting in malaria and tuberculosis control.

American personnel with the United States Health Mission in Burma have been successful in carrying preventive medicine to the areas outside the major cities. Venereal disease and malaria control teams have been trained and assigned to rural areas. Quarantine personnel have been trained. A nation-wide program in environmental sanitation is getting under way. American personnel serve as instructors at the Rangoon Medical School and Hospital. WHO and UNICEF are planning an extensive maternal and child health program in cooperation with the Government of Burma.

In Indonesia the small American public health group is providing advisory services to the Ministry of Health and assisting with the malaria control program carried on by the three malaria institutes. WHO and UNICEF are assisting in equipping 250 maternal and child health centers and are training personnel to staff these centers.

A nation-wide yaws eradication campaign carried on by WHO and UNICEF has resulted in treatment for more than 100,000 persons.

United States technical assistance in public health for the Philippine Islands is in the plan-

ning stage. However, WHO and UNICEF have established a rural training center and are carrying out extensive yaws and syphilis control programs in Leyte and Samar. A BCG production laboratory and a tuberculosis demonstration center have been established at Santa Cruz near Manila.

In Formosa the United States is assisting in the malaria control program and is providing advisory services to the government.

WHO has assigned public health nurses to Brunei, North Borneo, and Sarawak to strengthen the nursing institutions in these countries. In Malaya WHO is sponsoring malaria control programs and extensive BCG vaccination campaigns.

Malaria control activities in Thailand include blood tests, explanation of the program to school children, and supplying of aralen tablets. (Prints from a Mutual Security Agency film.)

DDT, Aralen, Education, Fight Malaria in Thailand

A local DDT spraying team is readying its equipment.

Here the team is carrying the equipment to one of the villages.

The people welcome the spraying team to the village.

The spraying team in action at one of the houses.

In Thailand, as in all of Southeast Asia, malaria is a major cause of death. Approximately 50,000 deaths due to malaria—about 20 percent of the total number of deaths—are reported annually. In addition, there are many more thousands of persons in the country who are partially or completely incapacitated and unable to work due to the ravages of this disease.

Malaria control activities began in April 1951 in the northern provinces of Chiangmai, Lampang, and Chiangrai. These activities were a part of the public health program established by the Thai Government with the assistance of an ECA public health mission, which was sent to Thailand in February 1951. ECA supplied DDT, spray equipment, jeeps, and aralen tablets, and Thai personnel carried out the spraying operations.

In a 3-week period, 400 Thai field personnel sprayed more than 40,000 houses with DDT. During this period, two ECA public health experts, a malariologist and an entomologist, were assigned to the northern provinces to assist, in an advisory capacity, the Thai malaria control officers.

An evaluation study was initiated in June 1951, to determine the accomplishments of the 1951 DDT house-spraying campaign and to develop plans for an extensive residual-spraying program during the 1952 malaria season. These plans include spraying activities to cover an area having some 1,400,000 persons.

The development and initiation of a program for the distribution of aralen tablets was less rapid than was the residual-spraying campaign. This was due to the desire of the public health mission to include as much village participation as possible, still making certain that aralen would reach all those who needed it in areas where spraying activities were going on. However, by August 1951, the distribution of aralen became routine field work in regions where malaria control teams were doing evaluation studies. At the end of August, approximately 20,000 aralen tablets were administered in the Province of Chiangmai, and a total of 200,000 aralen tablets were distributed in the five areas under study by the evaluation teams. Aralen is also being distributed as part of the trachoma control program, with the aim of reaching as many malaria sufferers as possible.

Much of the public health staff's malaria control activities during the latter part of 1951 were coordinated with the activities of the Thai Government to enable it to plan in full the 1952 antimalaria campaign. In addition to control measures for 1952, long-range plans include malaria control activities which should reach approximately 5,000,000 people within the next 5 years. As malaria control work becomes more firmly established, Thai personnel are taking over much of its supervision and direction. The aim of the public health mission is to enable the Thai Government to take over the malaria control program completely in as short a time as possible.

Through the Institute of Inter-American Affairs, the United States is cooperating directly with the governments of the various countries in Central America and the Caribbean area in carrying out health programs. The programs are being administered by cooperative government agencies known as "Servicios," which are staffed jointly by personnel from the United States and nationals of the host country and are financed by contributions from the United States and the host government. In all cases the host government supplies by far the major portion of both personnel and funds. Eight countries in this area are participating.

Caribbean Area

Technical Assistance in Public Health

In Costa Rica, the health program includes a project for the construction of sanitary privies, technical support to the Department of Sanitary Engineering in the Ministry of Public Health, and, jointly with the World Health Organization (Pan American Sanitary Bureau), financial assistance to the National School of Nursing.

Current activities in El Salvador include the completion and partial equipping of two hospital-health centers, a tuberculosis pavilion, and a nursing school, and the supervision of an extensive rural sanitation project emphasizing safe water supplies and sewerage systems.

The objective of the Guatemalan program is the completion of a 1,000-bed hospital and medical center on the outskirts of Guatemala City, for which Guatemala is furnishing the funds.

Major emphasis in Haiti is being placed on extensive campaigns aimed at the control of yaws and malaria, the two outstanding health problems of the country. Assistance is being given the control operations through clinics and mobile units, and an extensive health education activity is being carried out. Other current activities include the operation of a health center, technical guidance to the National School of Nursing, construction of additions to the water supply system of the capital city, and general cooperation with the Hydraulic Service of the Haitian Government in a program aimed at improving community water supplies.

The principal activities in Honduras now include malaria control operations, the construction of water and sewerage systems, and technical assistance in the operation of a national tuberculosis sanatorium in Tegucigalpa.

Since its beginning in 1942, the program in Mexico has placed special emphasis on the construction of water supply and sewerage systems. Other current activities include technical assistance to Servicio-constructed health centers, country-wide campaigns to control malaria, rickettsial diseases, tuberculosis, pinta, brucellosis, and Rocky Mountain spotted fever, as well as an extensive project to control venereal dis-

eases along the United States-Mexican border and smallpox in the Tepalcatepec River basin.

The program in Nicaragua was reactivated in January 1951. Current operations comprise evaluation of previous work, conducting of extensive surveys for water supply and waste disposal projects, and construction of two health centers and two water supply systems.

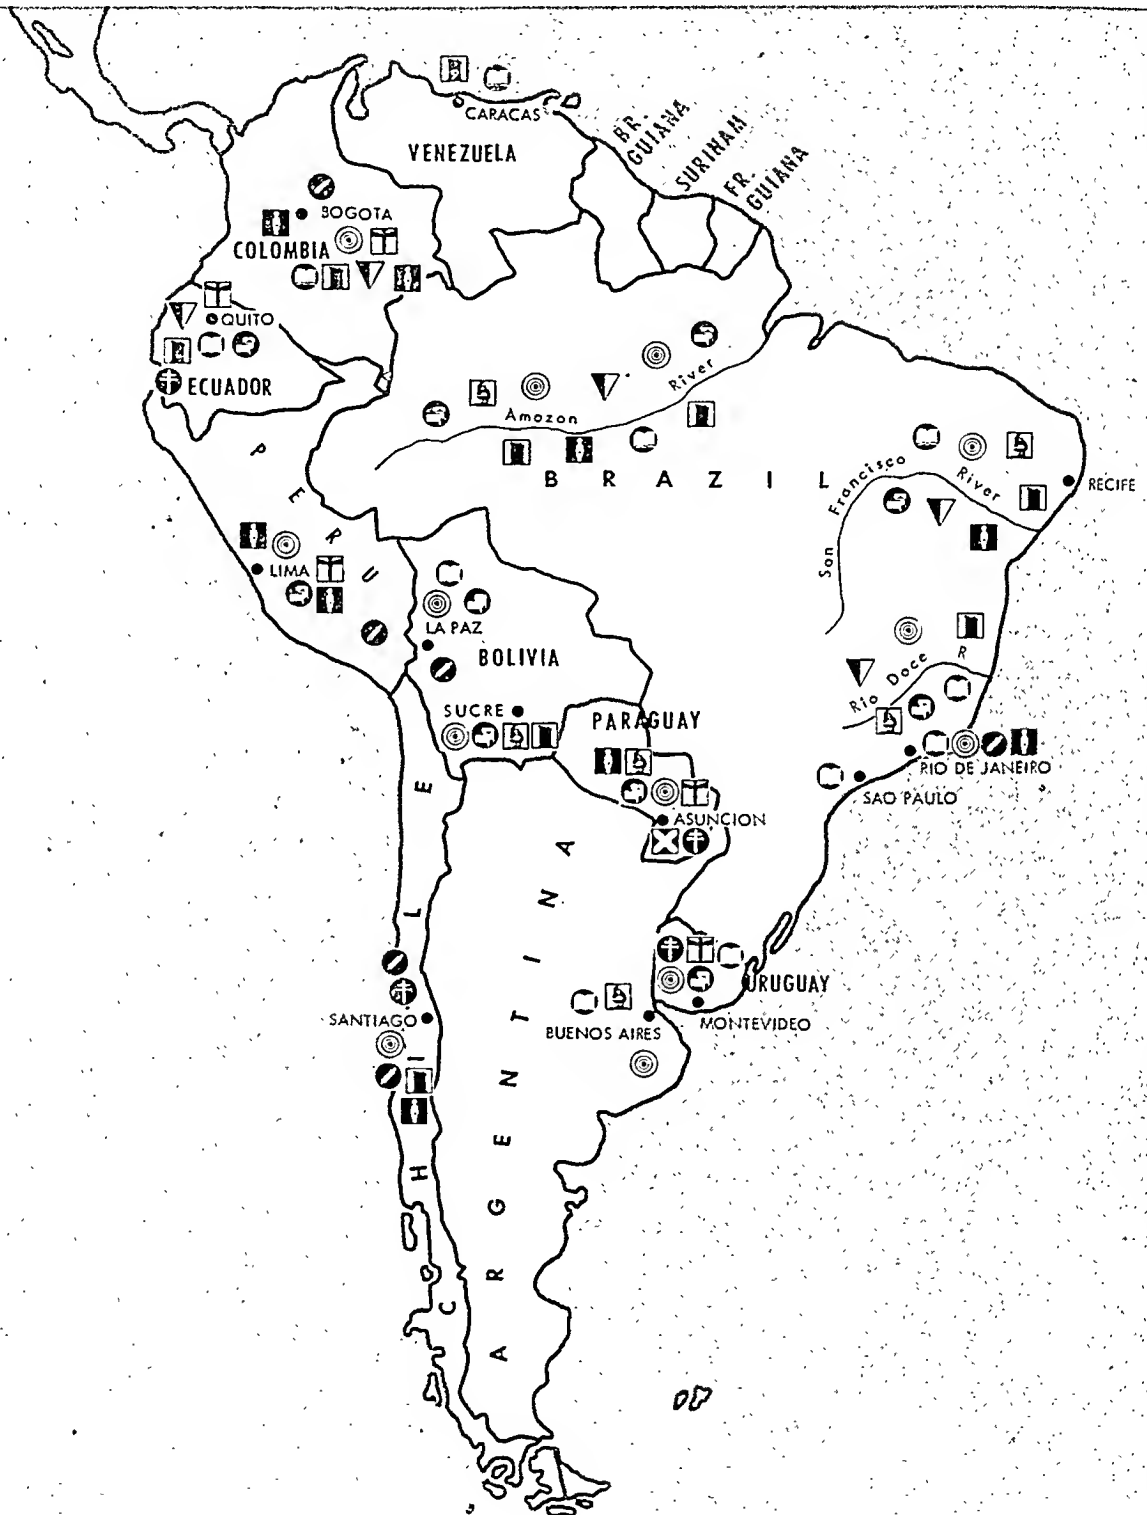

The Panama program, put back into operation in 1951 after a lapse of 6 years, is carrying on a country-wide health education project and making surveys for sewerage systems. The program also includes the operation of a country-wide BCG vaccination campaign against tuberculosis and technical assistance to the national hospital in Panama City.

The Pan American Sanitary Bureau acts as WHO's regional office for the Americas. It is continuing the campaign for the eradication of the *Aedes aegypti* mosquito, carrier of yellow fever. Joint WHO/UNICEF projects for tuberculosis control have been started in Costa Rica, where a 2-year program calls for tuberculin testing of 260,000 children and BCG vaccination of those not yet infected; in El Salvador, where it is hoped that 877,000 children can be tested and vaccination provided in 2 years; and in Jamaica, where the program calls for testing of 600,000 persons, vaccination, training of local personnel, and extending the services of an existing laboratory. A BCG vaccine laboratory in Mexico City, aided by WHO and UNICEF, produces vaccine both for Mexico and for other Latin American countries.

Campaigns against insect-borne disease are being conducted in Costa Rica, El Salvador, Guatemala, Honduras, British Honduras, and Nicaragua with WHO/UNICEF aid.

A 2-year campaign against yaws was launched in Haiti in 1950 with the cooperation of WHO and UNICEF. Venereal disease projects are being conducted in Nicaragua, Guatemala, and Mexico. The Institute of Nutrition for Central America and Panama was established in Guatemala with the cooperation of the WHO regional office.

South America

Technical Assistance in Public Health

THROUGH the Institute of Inter-American Affairs, the United States is carrying on bilateral technical assistance programs in health in nine South American countries. These programs are carried out through cooperative services similar to those used in the Central American countries. These "Servicios" are an integral part of the ministry of health in each country.

The major public health activity in Bolivia is the operation of a series of health centers in six of the country's nine departmental capitals. Other activities include the operation of dispensaries and a central laboratory, the training of personnel for laboratory work in health centers and hospitals, the supervision of country-wide health education projects, and the construction of a maternity hospital and a water supply system.

The cooperative health program in Brazil is centered principally in the Amazon, São Francisco, and Rio Doce Valleys and in the states of Bahia, Paraíba, and Pernambuco. Major activities include the operation of health centers (subposts in remote areas), hospitals, laboratories, and mobile dispensaries on river launches; construction of demonstration water supply systems, laundries, and public baths; state-wide privy construction projects in the states of Amazonas and Pará; studies relating to the incidence and control of yaws, schistosomiasis, and other diseases common in the areas; improvement of public health and hospital nursing services in five states; conducting of extensive health education projects; development of industrial hygiene; and technical assistance in hospital administration.

An important phase of the cooperative health program in Chile is the operation of three health centers serving areas with populations ranging from 30,000 to 80,000. Other activi-

ties include country-wide campaigns for the control of tuberculosis, typhus, typhoid fever, meningitis, diphtheria, whooping cough, and other diseases which have especially high morbidity rates in Chile. In progress also are a country-wide nutrition project, a technical assistance project in vital statistics, a project in sanitation for the Aconcagua Valley, construction of health centers and several sewerage and water supply systems for small towns, and a country-wide health education project.

Emphasis is being placed in Colombia on the control of malaria in an area with a population of 3,000,000. Nutritional deficiency studies, health centers and yaws control projects, a country-wide health education project, and the operation of the National School of Nursing are other activities of the Servicio. Industrial hygiene activities are being initiated and environmental sanitation projects expanded.

The present public health program in Ecuador is a broad one, involving the control of malaria and yaws, the construction of water supply systems in several small cities, the construction of improved sewerage systems, and on-the-job training of sanitary inspectors and laboratory technicians. Thirty-two hospitals

Technical Assistance in Public Health

have been constructed and are in use. The Servicio is also the administering authority for an Export-Import Bank loan used for the construction of water supply and sewerage systems.

Current activities in Paraguay include assistance to the leper colony and the operation of health centers, a central laboratory, and a 100-bed tuberculosis sanatorium, which is being expanded to 200 beds.

At the present time, activities in Peru include the operation of health centers, hospitals, dispensaries, medical and sanitary posts, and river launch dispensaries in the jungle area; the study of industrial hygiene problems particularly related to high-altitude mining; the control of yellow fever and leprosy in the Department of Loreto; the study of nutritional deficiency; and a nation-wide health education project.

The cooperative health program for Uruguay has been directed primarily toward the planning, construction, and operation of demonstration health centers in the important towns. The Servicio currently is operating four demonstration health centers. Other activities include a country-wide health education project, a yellow fever project, a tuberculosis project, and technical assistance to the University School of Medicine.

The public health center in Caméta, Brazil, is 1 of the 21 built in the Amazon Valley.

The United States-Venezuela cooperative public health program is now limited to two major fields of activity: the provision of small water systems for the many small towns throughout the country and technical assistance to the National School of Nursing.

The threat of yellow fever has been reduced in the Western Hemisphere in the past 4 years by the work of the Pan American Sanitary Bureau, which acts as WHO's regional office for the Americas. In Ecuador, joint WHO/UNICEF projects for tuberculosis control include testing of 1,100,000 children and adolescents, vaccination, and establishment of a vaccine laboratory in Guayaquil. In Peru, a campaign against typhus, which began in Cuzco after an earthquake in May 1950, has been extended, with WHO/UNICEF help, to the entire country. Venereal disease projects are conducted in a number of countries, including Ecuador; Peru, where control in a port area will be demonstrated; Venezuela, where a serologic laboratory and venereal disease training center has been opened in Caracas; and Paraguay.

Immunization of children against diphtheria and whooping cough is under way in Chile and Colombia. In La Paz, Bolivia, the country's first children's hospital is being erected with technical aid by WHO and UNICEF.

This combined hospital and health center was built by the United States-Brazilian Cooperative Health Service in Santarem, Brazil.

Health Programs Reduce Death Rate In Brazil's Jungles

In the region of the Amazon River, the United States (Institute of Inter-American Affairs)-Brazilian cooperative health program has produced some almost miraculous results. Disease and poverty in this jungle area have been rampant for centuries. Before the program began in 1942, there were, according to some Brazilian estimates, as many as 8,000,000 cases of malaria a year. Intestinal parasites victimized thousands of people. The death rate was almost unbelievably high.

An important part of the program to improve health conditions in the Amazon Valley is being carried on by the 27 public health centers which have been set up in various villages by the cooperative health service. These health centers have specialized clinics for expectant mothers, for tuberculosis, for dental care, and for venereal disease. They provide consultation and treatment for those in need of these particular types of public medical service. They carry out immunization programs against specific diseases, including smallpox, typhoid fever, diphtheria, whooping cough, and tuberculosis.

Each health center usually has on its staff a group of visiting nurse's aides who go out into the homes of the service area on daily rounds to bring advice and consultation, particularly on problems of child care and family nutrition. These nurse's aides have many and varied duties to perform in this area where doctors and trained nurses are few. They take blood samples, care for women during labor, give instructions on child care, and set broken bones. One of their most difficult tasks is to talk the people out of their fear of hospitals.

The health centers frequently have a staff of public health inspectors who make periodic check-ups on sanitary conditions in the markets, the restaurants, and other public places where food is sold or handled.

One of these public health centers is located in Caméta, a jungle village of 3,000 people. The results of the health program in this village have been particularly dramatic. The yearly death rate used to be 200 out of every 1,000.

The visiting nurse of the United States-Brazilian Cooperative Health Service provides a link between the health center and the homes.

By 1948, the rate was down to 90 per 1,000, and in 1949 it slid down to 70.

The health center in Caméta, opened in 1945, is staffed with a physician, a trained nurse, a pharmacist, three visiting nurse's aides, a sanitary guard, and a laboratory technician—all of them Brazilians. In 1949 the center treated, without charge, 19,727 patients, gave 5,417 injections, and filled 27,340 prescriptions.

Another important activity of the Cooperative Health Service in Brazil is the fight against malaria. The town of Breves, a village of about 900 people located 100 miles up the Amazon River, offers a good example of the results of the antimalaria campaigns. In 1945, this village was so saturated with malaria that the river boats would not stop there. That year DDT spraying activities were begun, and since that date the town has been sprayed twice a year. Today there is not a case of malaria in the town. The boats are stopping again, and the village has resumed shipping out rubber and lumber.

The health program in Brazil is being financed jointly by that country and the United States, Brazil furnishing nine-tenths of the funds and the United States one-tenth.

The Work of the World Health Organization

Expert Committees

In the conviction that our readers would find useful a review of the work of some of the expert committees of the World Health Organization, Public Health Reports asked leading authorities in this country who have participated in committee deliberations to report briefly on the activities of the committees. The editors are grateful for these contributions.

As described in the "Technical Reports Series" of WHO:

"Expert advisory panels and committees are an essential part of the machinery of WHO. Their purposes and functions are to provide the organization with technical advice on a particular subject.

"The Director-General has authority to establish expert advisory panels and to select and appoint their members, who undertake to contribute by correspondence and without remuneration technical information

or reports on developments within their own subjects; they serve in their personal capacity and not as representatives of governments, institutions, organizations, or other bodies.

"Members of expert committees are selected by the Director-General from the panels, the choice being governed by the agenda of each session.

"The selection of members of both expert advisory panels and committees 'shall be based primarily upon their ability and technical experience,' and 'due regard shall be paid to adequate geographical distribution.'

"Reports of expert committees express the corporate views of the members and are of basic importance as guides to the organization in the development of policies and programs. They do not, however, of themselves commit the organization to any policy or action; nor do they necessarily express the views of the organization. The publication of reports of expert committees is authorized by the Executive Board."

Environmental Sanitation

The significance of environmental sanitation as a process for alleviating disease on a world-wide basis was given a high priority among the First World Health Assembly's immediate objectives. The assembly early recognized that the failure to control man's physical environment or the inadequacy of implementing its regulation brings major deleterious effects to the majority of the population of the world.

The World Health Organization convened, therefore, the first session of its Expert Committee on Environmental Sanitation to delineate the functional areas in which sanitation should evidence the greatest results at a minimum of cost. The committee realized that in nearly all the countries of the world deficiencies in sanitary practice were major causes of disability and death and that progress in correction might be slow because of inadequate resources both of money and of professional personnel. Emphasis was placed upon (1) encouraging the early participation of professional engineers in governmental health activities; (2) giving high priority to the training of sanitation experts; (3) arousing the interest of national administra-

tions in the development of sanitation programs and in the modes of financing them; (4) demonstrating by WHO the coordination of environmental sanitation with other health activities in current assignments; and (5) the developing of demonstration teams having both technological and educational objectives.

Significant progress on these fronts has already taken place despite long and extensive delays which essentially represent processes of education of both medical officer and engineer. The kind of practice that has grown up in sanitation in the United States, the United Kingdom, and a few other areas serves, perhaps, no more than 20 percent of the population of the world. The translation and adaptation of these values to the cultures, practices, and structures of other countries is a slow evolutionary process. Since none of these activities are the exclusive professional province of any one group, the integration of sanitation work into the team objective of medical officer, nurse, and laboratory worker offered early challenges. More and more in each country, the medical officer's concept has become wider

and deeper, and his natural leadership of team activity has been extended to the acceptance of more engineering sanitation participation.

However, the mere handful of sanitary engineers in the world (probably not more than 10,000) could not be expected to provide the leadership essential for these activities in a world population of more than 2 billion without developing on all fronts almost every gradation of professional and subprofessional sanitation worker.

A second committee session was therefore convened in October 1951 to devote its attention to the specific problem of the education, training, and utilization of personnel for environmental sanitation. The report of this committee proposed qualifications, training, and functions for engineers, plant operators, specialists, industrial hygiene personnel, sanitarians, and voluntary lay leaders. It re-emphasized the great desirability of maximum teamwork with the medical officer of health, the nurse, the health visitor, and other personnel engaged in health other health personnel.

ABEL WOLMAN, B.S.E., Dr.Eng.,
Professor of Sanitary Engineering,
The Johns Hopkins University

The executive board of the World Health Organization recommended at its third session the establishment of an Expert Committee on Antibiotics to deal with research in antibiotics and various technological problems. This committee held its first meeting in April 1950.

The problems considered were mainly concerned with the production of antibiotics; training and research; feasibility of international conferences on antibiotics; abstracting service; type culture collections; surveys of penicillin requirements; modernization of UNRRA penicillin plants; production of streptomycin; the present position of antibiotics; and development of research in therapeutics.

Design of antibiotic plants and procurement of equipment and personnel presented the main difficulties which prevented certain countries, especially those of eastern and central Europe, and some underdeveloped areas, from producing penicillin and other antibiotics. The committee recommended that WHO assist member states in procuring

essential equipment and that it provide assistance in collaboration with the economic organs of the United Nations to countries unable to obtain the necessary currencies.

The committee also recommended that WHO assist member states to use available training facilities for creating teams of highly trained scientific and microbiological engineers; that WHO grant fellowships for one year or more to persons with a sound knowledge of chemistry, engineering, or microbiology to enable them to take part in research work in antibiotics; and that it negotiate with institutes having appropriate training facilities for acceptance of WHO fellows as participants in their research programs.

Several institutes offered facilities for training such personnel: the Department of Microbiology, Rutgers University, New Jersey; the Department of Biochemistry, University of Wisconsin; the Nobel Institute of Medicine, Stockholm; the University of Oxford, England; and the Istituto Superiore di Sanità, Rome. The first training center has been established

at the latter institute, and a special symposium was held there at the end of June 1951.

The committee proposed the organization of a symposium to discuss primarily the newer antibiotics now finding application in chemotherapy, and the relation of antibiotics to tuberculosis and venereal diseases.

It also recommended that the Expert Committee on Biological Standardization be given support in obtaining international standards and reference preparations for antibiotics which, although in the experimental stage, would appear to be of importance.

Attention was drawn to the unsatisfactory terminology sometimes used in the assay of new antibiotics, and attention of authors and editors of scientific journals was directed to the preference for the use of the term "provisional unit" in place of "unit."

SELMAN A. WAKSMAN, Ph.D.,
Chairman, Department of Microbiology, Rutgers University

Biological Standardization

The work of the Expert Committee on Biological Standardization follows in orderly sequence from Ehrlich's original work in 1894 on the standardization of diphtheria antitoxin. The task of the committee is to re-evaluate and replace the old standards as required and to establish standards for the newer biological substances, such as antibiotics, hormones, and enzymes, as rapidly as they can be characterized. Some means of standardization must be developed before newly discovered substances like adrenocorticotrophic hormone (ACTH) can be introduced into rational therapeutics.

At the fifth session of the committee, held in Geneva in December 1951, steps were taken to improve the old standards, as in the case of diphtheria toxoid, as well as to develop

standards for the newer substances such as the antibiotics and hormones. The scope of the work has expanded greatly from the classical immunological preparations to a wide variety of biological substances, including diagnostic antigens and serums, antibiotics, hormones, and enzymes. In an effort to keep abreast with new developments, steps were taken to establish a collection of authors' preparations.

The scope of the work of the committee was broadened at the request of international organizations interested in veterinary medicine to include certain preparations requiring standardization for use in research and in medical practice in that field. This is a logical development since frequently the same substance, for example tuberculin, serves equally well in both human and veterinary medicine.

Many of the products for which biological standards have been established now appear in the Pharmacopoea Internationalis I, and it is obvious that the two committees concerned must work closely together.

Much remains to be done in biological standardization. For example, there is still no usable reference preparation for as old a product as rabies vaccine. Then, too, research developments in the newer fields with antibiotics, hormones, and enzymes are just getting under way, and standards or reference preparations will be required for the drugs resulting from this research as they come into everyday use in medical practice.

WILLIAM G. WORKMAN, M.D.,
National Institutes of Health, Public Health Service

An expert committee of the World Health Organization and two joint groups of the Food and Agriculture Organization and the World Health Organization have been set up to advise on the control of a group of diseases common to both man and animals.

Rabies

Treatment with rabies hyperimmune serum combined with a course of vaccine was recommended for field trials in human beings by the WHO Expert Committee on Rabies at its meeting in Geneva in April 1950. Experimental findings show that the serum preceding a course of vaccine gives promise of saving most of the severely exposed human rabies cases in which short incubation time does not allow the development of active immunity.

Iran was designated for the trials. Rabid wolves bit 60 persons in 1949, and 22 persons were bitten during the first 4 months of 1950. These cases are always severe and at least half the victims are bitten in the head and face. The mortality rate exceeds 30 percent despite intensive vaccine treatment. The hyperimmune serum treatment would thus be subject to severe test.

The committee also urged further ecologic studies on vectors of the disease. The existence of asymptomatic carriers was recognized from observations of vampire bats as rabies vectors in South and Central America.

To reduce to a minimum the number of people subjected to antirabic treatment unnecessarily, the committee suggested the following indications for vaccine treatment: A person treated with vaccine and exposed to rabies a second time within 3 months needs no further treatment unless the second exposure is severe; if the interval is between 3 and 6 months, two reinforcing doses of vaccine, 1 week apart, are indicated; if more than 6 months have passed, treatment should be the same as for an original exposure.

Allergic reactions to vaccine treatment, such as fever, shock, angioneurotic edema and adenopathy may be avoided by changing to a vaccine made from the brain tissue of a different species of animal.

The committee recommended that, where feasible, a biting animal should be observed for 10 days. If the animal shows no signs of illness during this period, it can safely be assumed that it was noninfective.

Where restrictive measures only are used to control rabies, dogs should be confined for at least 90 days, if vaccine is used. This period may be reduced to 30 days after vaccination. The committee recommended that exposed animals be destroyed or isolated for 6 months or, if vaccinated within 12 months of exposure, revaccinated and isolated for 30 days.

In extensive land areas where rabies exists among domestic and wild animals, the committee recognized that quarantine measures are impractical.

Brucellosis

Strain 19 vaccine was thought the best available to combat brucellosis by the Joint FAO/WHO Expert Panel on Brucellosis which met in Washington, D. C., in November, 1950. This vaccine approaches the ideal as defined by the panel: it confers adequate protection; it is safe, that is, it is dead or relatively avirulent and shows no tendency to increase in virulence in the animal body; it causes a minimum of interference with the seroagglutination test; and it is easy to produce, preserve, and distribute.

In discussing control and eradication procedures for bovine brucellosis, which are based on the elimination of infected animals or vaccination, the panel agreed that the tube seroagglutination test is one of the most reliable methods for detecting infection in individual animals. The rapid plate test is very good, too, when standardized with the tube test. The ring test for milk is

valuable to locate infected herds or milk supplies.

Although the problem was limited, the panel recommended that infected herds of goats, sheep, and swine be slaughtered if the infection was new to the area, as there are no satisfactory vaccines for these animals.

The panel reviewed bacteriological culture and typing of *Brucella* and recommended criteria for final identification. FAO and WHO have established 12 brucellosis centers for control of the disease in animals and man. To stimulate eradication programs, the panel urged the reporting of the disease.

Human brucellosis was discussed by the panel under clinical criteria, diagnostic criteria, and therapy. The value of these subjects was studied before the panel reported their conclusions. Routes of transmission from animals to man were also discussed.

Zoonoses

More than 80 zoonoses, "those diseases which are naturally transmitted between vertebrate animals and man," including virus, rickettsial, bacterial, fungus, protozoal, helminth, arthropod, and insect diseases, were listed by the Joint WHO/FAO Expert Group on Zoonoses at its 1950 session in Geneva.

Bovine Tuberculosis

The most important disease problem considered was bovine tuberculosis. The group recommended tests for detection and slaughter as a highly effective method for controlling the disease. Several countries have almost eradicated the disease with this technique.

As a temporary expedient in special circumstances, vaccination was suggested. The limitations of BCG use for cattle are: the animals react to tuberculin for at least 1 year, and this can interfere with the test and slaughter program; the intravenous use of BCG vaccine, as observed in the United Kingdom, may cause undesirable systemic reactions; the large unsightly swellings

which frequently follow subcutaneous use of BCG may be objectionable to the herd owner; and adequate and fresh supplies of the vaccine are frequently difficult to obtain in certain areas and countries.

The group also pointed out the importance of protecting the animals against human carriers and recommended health supervision of milkers and attendants.

Q Fever

The group suggested local and regional surveys to determine the prevalence of Q fever in man and animals; research on diagnostic tests other than the complement-fixation test; immunization of domestic animals, and chemotherapy for man and animals.

Anthrax

To control agricultural outbreaks of anthrax, the group recommended

the establishment of local diagnostic facilities, low-cost or free livestock vaccination, and that rural populations be taught to recognize the early signs of anthrax in man and animals.

Psittacosis

Re-examination of quarantine policies on psittacosis was recommended by the group in the light of new knowledge of wider disease reservoirs, the lower prevalence, and successful use of antibiotics in treatment of human cases. Although the group supported the prohibition of commercial shipments, they suggested easing quarantine regulations for individual pets, rare birds, and breeding stock.

Hydatidosis

Successful control of hydatidosis requires the reduction of the disease

in its animal reservoir, the dog in most cases. Two points for its control were emphasized by the group—eradication of canine infection by anthelmintic treatment and stray dog control, and sanitary animal slaughter and prevention of infection.

Virus encephalitides, leptospirosis, tularemia, bilharziasis, trichinosis, glanders, and salmonellosis were discussed for future action. The group recommended food hygiene problems for early study by WHO and FAO and also recommended the development of international standards for veterinary biological products in conjunction with other groups working on the same problem.

Communicable Disease Center, Public
Health Service

Nursing

The Expert Committee on Nursing was first convened in February 1950 to advise the World Health Assembly on measures to insure the recruitment of nurses in proportion to the needs of each country and to advise on the education of nurses.

The committee recommended that WHO urge each member government to take an inventory of its nursing personnel, including auxiliary nursing personnel, and to estimate the number of each type which would be needed by the developing health programs in each country. A manual was sent to each member government to assist the proper authorities in surveying the nursing resources and needs of the nation. The surveys, the committee hoped, would provide a basis for more specific and long-range planning, and would focus attention on the needs for nurses of all types and on methods for filling the needs.

Attention was called to a few simple principles of nursing education, including the desirability of sound professional leadership and careful selection of students. The committee recommended that WHO

undertake fundamental research with the assistance of social scientists to determine the health needs of people in two or more societies. The results of this study, the committee believed, would serve as a basis for realistic and pertinent designs for nursing education in various countries. It would help avoid duplication of an established pattern, like that of the United States, in countries where the cultural patterns and health developments are vastly different.

The committee noted the opportunity for cross-representation of health disciplines on several committees, including the Expert Committees on Maternal and Child Health and on Professional and Technical Education. It also emphasized the importance of granting fellowships to several types of health workers from one country to provide teams that could work together in that country after study abroad.

The committee's task at its second meeting in October 1951, was to advise on the provision of nursing service and the preparation of nursing personnel in areas of the world where

nursing services are scarce. The importance of the inclusion of health in the "fundamental education" programs of UNESCO and other specialized agencies was discussed. A few examples of nursing service that meet a variety of needs of the people were collected and included in the report, most of them from the countries where health programs in nursing are new aspects of national life.

The committee strongly recommended that, in the schools of nursing in such countries, students be given instruction and experience in teaching and supervising untrained auxiliaries. Nurses graduated from one of these schools, regardless of previous educational background or quality of training, will be expected to assist in establishing health services in situations where no other health workers exist. The committee was concerned with obtaining translations of original work on practical health subjects for use in nursing schools and in community health programs.

LUCILE PETRY, R.N., M.A.
Chief Nurse Officer, Public
Health Service

Drugs Liable to Produce Addiction

The Expert Committee on Drugs Liable to Produce Addiction is advisory through WHO to the United Nations and its Commission on Narcotic Drugs. On the international level it formulates an opinion on the addiction producing properties of a drug and under some circumstances indicates the degree of control to which the drug should be subjected. It also discusses and makes recommendations on general problems in the field of drug addiction. The committee has met three times, in January 1949, 1950, and 1952.

The committee has declared to be addiction producing the drugs methadone, meperidine, and about a dozen derivatives of these synthetic analgesics, and has recommended that, like morphine, they be subjected to international control. A similar recommendation has been made for 3-hydroxy-N-methylmorphinan (Dromoran), its codeine analog, and a number of new morphine derivatives. It has considered also the addiction liability of a number of commercial preparations of morphine-like substances as a basis for continuance or relaxation of their international control.

The committee has drafted definitions of drug addiction and addiction producing drugs on the one hand and of habituation and habit-forming drugs on the other hand, and has

recently appended to these definitions a statement to clarify the distinction it believes can and must be made between these two conditions and the drugs producing them.

Much thought has been given to the gravity of the heroin situation, and the committee is of the opinion that complete abolition of legally produced heroin in the world would greatly facilitate the struggle against illicit use of this substance. On its recommendation the Director-General of WHO has inquired of governments throughout the world why their physicians consider heroin necessary in medical practice. Although in 1949 only 24 nations were known to have discontinued the use of heroin, replies now show that 50 member states of WHO have discontinued or are willing to discontinue the medical use of the drug. This changing attitude on the part of the medical profession prompted the committee to recommend that WHO pose to the remaining nations the direct question, whether or not they could do without heroin in the interest of public health and safety.

The committee has reviewed the increasing use and abuse of barbiturates throughout the world. Barbiturates, the committee believes, must be considered drugs liable to produce addiction and, therefore,

dangerous to public health. It advises that nations take measures to strengthen control of these drugs.

At its first session the committee recommended the establishment of a mechanism for the selection of common nonproprietary names, especially for addiction producing drugs which come under international control. As a result the WHO Expert Committee on the International Pharmacopoeia has set up a Subcommittee on Nonproprietary Names. The names selected are now used by the Permanent Central Opium Board and Drug Supervisory Body in all of their documents, and governments are urged to use these names whenever possible.

Great activity has been shown in recent years in the development of synthetic morphine-like analgesics. So far all of the new substances of merit otherwise have been addiction producing; nevertheless this line of investigation should and will continue. WHO's Expert Committee on Drugs Liable to Produce Addiction will continue to keep the closest watch on developments in this field and must continue to play a most important role in assessing the inherent dangers of all analgesic drugs.

Health Service

Epidemiology and Quarantine

The Expert Committee on International Epidemiology and Quarantine is the Nestor of WHO committees. When the amalgamation of the epidemiological services of the League of Nations, UNRRA, and the Office International d'Hygiène Publique had been recommended by the International Health Conference in New York, the Interim Commission of WHO, at its first session in July 1946, appointed a Committee on Epidemiology and Quarantine. The functions of this committee included supervision of the application

of the international sanitary conventions and of any other measures necessary to check the spread of epidemics across national frontiers.

The responsibilities inherited from UNRRA included the delineation of yellow fever endemic areas and the approval of yellow fever vaccines according to the international sanitary convention of 1944. Subsequently, study groups were set up on cholera, smallpox, plague, and typhus. When WHO became a permanent specialized United Nations agency in 1948, the committee

received the status of a regular expert committee.

Meanwhile it was realized that the existing international quarantine conventions were scientifically outmoded. Furthermore, the failure of many governments to ratify the more recent conventions had brought about a state of confusion in matters relating to quarantine. The First World Health Assembly therefore directed the Expert Committee on International Epidemiology and Quarantine to draft new international sanitary regulations to replace

the existing quarantine conventions.

Draft regulations were prepared by the expert committee in December 1949. The Expert Committees on Insecticides and on Plague, the Study Group on Cholera, and the Yellow Fever Panel had met previously and made valuable contributions. The draft was submitted to governments for comment, and revised by the committee in October 1950 to include a number of the suggestions received. In April 1951, a Special Assembly Committee, consisting of official delegations from member states, met in Geneva for 4 weeks to discuss the revised draft and approve a text. After minor

amendments, this text was unanimously voted by the Fourth World Health Assembly on May 25, 1951. The regulations are to go into effect October 1, 1952.

For the first time in history, uniform quarantine regulations will be applied throughout the world, and an ideal worked for during a whole century will have been attained. Impediments to international traffic for purposes of epidemic control have been limited, and better protection against pestilential diseases has been obtained.

The committee's quarantine section has, among other problems, dealt with complaints from govern-

ments concerning the application of the international sanitary conventions.

The Expert Committee on Plague produced, in 1949, a detailed outline of plague control field work and of procedure in the elimination of reservoirs and vectors of plague in sea- and airports.

The Joint ILO/WHO Committee on the Hygiene of Seafarers dealt with subjects not included in the sanitary regulations but, nevertheless, of importance to international travel and transportation.

Division of International Health,
Public Health Service

Malaria

The Expert Committee on Malaria in its fourth session held at Kampala, Uganda, December 1950, reaffirmed the policy formulated in its earlier sessions (1947-49) for the World Health Organization. The committee recommended that the highest priority be given to malaria control in any WHO program of technical assistance to highly malarious areas. The committee emphasized the continuing need for active encouragement of malaria control by all means within WHO's province.

The committee recommended that the assignment of malaria control demonstration teams to underdeveloped areas be continued and that these teams be staffed with men engaged on a long-term basis. The term of each team should be of at least 3 years' duration. By these means a reservoir of trained staff would be constantly available. The teams should be sent to areas in which no adequate demonstration of the utility of modern measures of malaria control have as yet been made. One of the chief functions of such teams would be to assist in the development of local organizations and in the training of staff. Short-term field fellowships and travel grants for training in malariology were recommended as more useful than long ones.

The Expert Committee on Malaria

approved the recommendations of the Malaria Conference in Equatorial Africa and recommended that WHO impress on member states and on the Commission for Technical Cooperation in Africa South of the Sahara (CCTA) the importance of implementing these recommendations. WHO with the cooperation of CCTA, where relevant, should establish, the committee felt, an annual malariology course in Africa and offer help to one or more member states which undertake malaria control in large areas where the adult population has a high degree of tolerance to the disease.

The committee agreed with the recommendations of the Expert Committee on Insecticides regarding the method and timing of the disinfection of aircraft and with the composition, dosage, and methods of distributing insecticides in aircraft. It recommended that WHO increase the practical value of the specifications laid down by the insecticides committee for spraying apparatus by preparing specification charts of sprays now on the market.

In the prevention of the spread of anopheline vectors of malaria by international transport, the Expert Committee on Malaria agreed with the Expert Committee on Insecticides on techniques to be employed and recommended that an interna-

tional agreement be sought on the basis of the designation of the international airports according to their degree of infestation rather than on a designation of countries or other large areas in this regard.

The committee reaffirmed its position on measures taken by the Economic and Social Council of the United Nations, the World Health Assembly, and other bodies to promote the free flow of insecticides, insecticidal formulation, raw material and equipment for their manufacture, and the apparatus for their application. It approved the United Nations' suggestion that the best means of implementing the pertinent resolution of the World Health Assembly would be through the medium of an international agreement. The committee emphasized that, as noted in its third report, experience has proved residual spraying to be a measure of major importance. A monograph on therapeutics and revision of malaria nomenclature were recommended.

G. ROBERT COATNEY, Ph.D.,
National Institutes of Health, Public
Health Service

The activities of the Expert Committee on Insecticides will be described in more detail by Dr. Samuel W. Simmons in a paper scheduled for publication in a subsequent issue.

In the past 5 years, outstanding accomplishments have been made in the field of international health statistics. Most notable was the agreement reached at the Sixth International Decennial Conference for the Revision of the International List of Causes of Death (Paris, 1948). This agreement led to the international adoption of a single statistical classification for illness and causes of death.

Scarcely less important was the conference's sweeping five-point proposal, later adopted by the World Health Assembly, for international cooperation in vital and health statistics. These five recommendations and the action that followed them are summarized below.

1. An Expert Committee on Health Statistics was created by the World Health Organization. Three meetings have been held, with these principal results:

At the committee's request, the World Health Organization established a center to adjust problems arising in the application of the international statistical classifica-

tion. This world focal point for clearing this type of problem has been operating since January 1, 1951.

International definitions were established for live birth and foetal death, and the collection of comparable data in this area was stimulated.

Intensive work was done on problems of cancer statistics and hospital statistics.

International needs in the broad aspects of morbidity statistics were reviewed.

2. National Committees on Vital and Health Statistics have been created by 35 member nations. These committees are a powerful force in promoting national health statistics. Moreover, by studying problems referred to them by the expert committee, they provide a channel through which ideas from national sources reach international levels for consideration and action. Thus, a mechanism has been established for assuring direct national participation in solving international problems in health statistics.

3. The recommendation that the World Health Organization develop its statistical service led to creation of a WHO statistical unit that serves not only the needs of WHO but also as a secretariat for the expert committee.

4. The Paris conference recommended occasional international technical conferences on problems in vital and health statistics. At its third meeting, the expert committee proposed that WHO call an International Conference of National Committees on Vital and Health Statistics in the spring of 1953, and suggested items for the agenda.

5. In promoting international health statistics, WHO is cooperating with the interested services of the United Nations and specialized agencies, particularly with the Statistical Office of the United Nations, which has responsibility for collecting vital statistics and establishing vital statistics standards.

HALBERT L. DUNN, M.D., Ph.D.,
National Office of Vital Statistics,
Public Health Service

Maternity Care

The WHO Expert Committee on Maternity Care, meeting in Geneva in November 1951, considered all aspects of maternity care and its importance to the health and well-being of all communities.

The committee endeavored, as far as information was available, to keep clearly in sight the differing stages of economic development in various parts of the world, and the differing needs in this field as well as in other aspects of public health. Although the committee realized that one comprehensive plan cannot be applied in all countries, it agreed on certain standards of maternity care for implementation in stages, over a period of time, in countries where there has been little development. At the same time, the committee considered that the development of maternity care has not always proceeded soundly in the economically more developed

countries. The committee recommendations are designed to serve as a guide to governments instituting this service.

Maternity care is closely linked with existing social, labor, and educational services, and many of these services offered by governmental agencies are needed to supplement any sound program of maternity care. Hence, the committee emphasized that it is important for governments to recognize the desirability of cooperation between such agencies at a national level. The committee stressed also that maternity care should be regarded as an integral and important part of any broad public health program.

The transcendent importance of the training of midwifery personnel, especially for underdeveloped countries, was reviewed at length and a recommendation made to the World

Health Organization that a joint expert committee, composed of members of the advisory panels on nursing and maternal and child health, be convened to give further consideration to the training of midwifery personnel at all levels. Prior to the convening of such a joint committee, information regarding the present patterns of maternity service and the training of personnel will be collected from various countries. This is in keeping with the general recommendation of the committee that the World Health Organization undertake fundamental research to determine the real health needs of peoples and to study, in this connection, the need for maternity care and the way in which it can best be satisfied.

NICHOLSON J. EASTMAN, M.D.,
The Johns Hopkins Hospital, Baltimore, Maryland

Upon its organization, the Expert Committee on the International Pharmacopoeia of the World Health Organization drew upon a rich heritage of nearly 50 years of endeavor. Although there was earlier interest in an international pharmacopoeia, the year 1900 saw the first formal action among nations. The resulting Brussels Conferences of 1902 and 1925 and the establishment in 1937 of a Technical Commission of the Health Organization of the League of Nations had the purpose of unification of national pharmacopoeias. Thus, one of the first functioning groups created within the WHO in 1947 was the Expert Committee on the Unification of Pharmacopoeias, which took up the work retarded but not entirely interrupted by the war. It was apparent that achievement of the desired end was most feasible through the preparation of an international pharmacopoeia. Indeed, it was for this reason that the name was changed to the Expert Committee on the International Pharmacopoeia.

Because of the pre-existing groundwork the committee's efforts produced results quickly in the form of volume I of the Pharmacopoeia Internationalis, published last October. Volume II is in preparation for release late this year. The two vol-

umes, to be available in English, French, and Spanish, will provide standards of strength, quality, and purity for nearly 300 basic drugs in the forms found useful generally in accepted medical practice. In addition to therapeutic agents, including the antibiotics and other established chemotherapeutic drugs, diagnostic aids and immunological preparations are covered. Numerous appendixes provide the required general pharmaceutical and bacteriological tests and tables of usual and maximal doses for adults and children. Included is the serodiagnostic test for syphilis, using cardiolipin and purified lecithin.

An important aspect of the committee's work is the selection for international adoption of common, nonproprietary names of drugs. This program to eliminate a growing state of confusion among pharmacists and physicians will coordinate the efforts of several national bodies now selecting names for drugs.

Addenda will be issued to volumes I and II of Ph. I. until a complete revision is made. Plans call for a revised edition printed as a single volume about every 5 years. This program will keep the compendium up to date and will insure its continued usefulness, especially to the

great majority of the 79 member states of WHO which do not have a national pharmacopoeia. It will also enhance the value of the Ph. I. to the few countries, such as the United States, England, and France, which now have an active pharmacopoeial revision program.

A book of standards for purity and potency of drugs is essential to any national health program. This principle has been recognized in many countries to the extent that the national pharmacopoeia has legal recognition and is binding upon pharmacists and drug manufacturers. In many of the countries without national pharmacopoeias, the Ph. I. will probably be adopted legally. Elsewhere, independent preparation of national pharmacopoeias has resulted in a lack of uniformity that causes confusion and danger to travelers and is a hindrance in the utilization of scientific information. With the Ph. I. as a model, these inconsistencies will decrease even though the book is not given legal status. These are but part of the benefits expected from the efforts of the Expert Committee on the International Pharmacopoeia.

LLOYD C. MILLER, Ph.D.,
Director of Revision of the Pharmacopoeia of the United States of America

Mental Health

Because of the tremendous shortages in trained psychiatric personnel and in facilities from a world-wide viewpoint, the first meeting of the Expert Committee on Mental Health recommended that the World Health Organization accept the preventive principle in the application of psychiatric knowledge as the most practical approach to its mental health program.

The suggested standard for adequate care is one psychiatrist per 20,000 population. The United States has more than 5,000 psychiatrists and about 700,000 psychiatric beds, but India, for example, with more

than twice the population, has at most 80 psychiatrists and 20,000 psychiatric beds. Hence, the only practical approach, the committee was convinced, was through preventive measures.

Meeting at Geneva, Switzerland, August 29 to September 2, 1949, the committee was composed of psychiatrists of six nationalities. Twenty topics were discussed and recommendations made on 19. Among the 19 were principles and priorities in mental health, health education, alcoholism and drug addiction, maternal and child health, and venereal diseases.

In each discussion the committee was confronted with the problem of inadequate numbers of trained personnel. The committee concluded that perhaps the most effective method to implement a mental health program would be through the use of public health workers.

A concrete point on which WHO could give assistance to member nations was the recommendation that it aid in the development of facilities for training public health workers in the principles of preventive mental health work, in training workers in clinical psychiatry, and in assisting pediatricians and other physicians to

obtain psychiatric and mental hygiene training.

The committee's second meeting at Geneva in September 1950 was, therefore, devoted to consideration of the application of mental health principles through public health workers, and how the job could be done.

As a result of this consideration, the mental hygiene section of WHO subsequently convened a committee

of experts on alcoholism and the original committee as such was discharged. Thus, through an ad hoc committee of specialists in a limited area, more productive results could be expected.

The significance of the expert committee plan of WHO as it applies to mental health and psychiatry was:

National and cultural experiences were brought together on a world basis. The common denominators

of these widely varying experiences were used to try to develop potential world-wide application. The recommendations of the committee, once approved by the World Health Assembly or the Executive Board, could be passed on as authoritative statements to the chief health officers of the member nations.

WILLIAM C. MENNINGER, M.D.,
The Menninger Foundation, Topeka,
Kansas

Venereal Infections and Treponematoses

Venereal diseases have been recognized as an urgent international health problem from the earliest days of WHO. An Expert Committee on Venereal Diseases was formed by the Interim Commission and has functioned continuously since January 1948, when its first meeting was held. The committee has met twice since that first session, in Paris in 1948 and in Washington in 1949.

In outlining the principles and scope of an international program to combat venereal diseases, the committee gave first priority to the control of syphilis, followed by gonorrhea, chancroid, lymphogranuloma venereum, and granuloma inguinale, in that order. Treponemal diseases such as bejel and yaws, which constitute grave health problems in tropical and subtropical areas, have since been added to its terms of reference. Of the forms of syphilis, the early infectious stages and infantile and prenatal syphilis have received major emphasis.

Because penicillin therapy permits an approach to control of treponemal infections in terms of whole population groups, the committee has recommended WHO aid for control work in economically underdeveloped areas where prevalence of one or more of the treponemal diseases is high. It has also urged the importance of assisting countries to establish a basic venereal disease control structure headed by a health officer specializing in venereal diseases. From its first meeting, the group has pointed out the need for training in venereal disease work through demonstrations, consultative services, and fellowships, and for distribution of venereal disease literature and reference lists.

As an outgrowth of a recommendation of the committee in 1948, a Subcommittee on Serology and Laboratory Aspects was formed, and has held two meetings. Establishment of this group reflects in a concrete

way the committee's belief that effective control of syphilis depends to a large degree upon efficient serologic testing. The serology subcommittee has placed emphasis upon evaluating the efficiency of the various serologic tests, distribution of test antigens, and standardization of laboratory procedures.

The committee has expressed its belief that specialized health programs will prove most productive, on a long-term basis, if supported by a general program of disease prevention. Demonstration teams in venereal disease control and other specialties may prove valuable aids not only to combat specific health problems but also as beginning points from which over-all health programs may evolve.

JOHN F. MAHONEY, M.D.,
Commissioner of Health, City of New
York

Nutrition

Malnutrition and even outright starvation are major causes of illness and death in many nations. Furthermore, no country, no matter how abundant its food supply, can afford to take the complacent view that abundant food automatically confers optimal nourishment.

Malnutrition is preventable. The scientific principles and practices by which nutritional health can be produced and maintained are known. However, these facts have not been

disseminated to all the peoples of the world. The application of this knowledge is further limited by traditional but improper dietary practices, by qualitative deficiencies in available food, and, unfortunately in some countries, by insufficient quantities of food.

Two international organizations, the World Health Organization and the Food and Agriculture Organization, have recognized these facts and the programs of each have the com-

mon objective of raising levels of nutrition throughout the world. Action programs must be tailored for each nation according to the nature of its nutritional problems and to the many factors which may be producing the problems.

To advise and assist in attacking this complex situation, a joint WHO/FAO Expert Committee on Nutrition was convened in 1949 and 1951. The 10 members are appointed, 5 by each organization, to

provide the highest technical competence and to obtain geographic representation.

The action programs of FAO and WHO are administered separately but coordinated closely both internationally and regionally. The joint expert committee also assists and advises in coordinating and in delineating the activities of the two organizations. In FAO programs, emphasis is on the production, distribution, and consumption of food, while in WHO it is on nutrition in relation to the maintenance of health and the prevention of disease. The FAO program, which is somewhat older than that of WHO, can point to many outstanding accomplishments. Internationally accepted data on world food consumption, calorie requirements, nutrition facts for educational purposes, and approved techniques for dietary surveys have been published and have found wide use. WHO has focused on studies

of nutritional deficiency diseases, such as kwashiorkor, endemic goiter, problems of infant feeding, and on methods for the determination of nutritional status. Internationally acceptable standardized methods for the latter purpose are being prepared by the committee. Both FAO and WHO have provided fellowships for training in nutrition and have provided expert consultants and direct technical assistance to member governments. They have conducted workshop training courses and can take much credit for instituting or improving nutrition services in many governments.

Much remains to be done. Agreement on internationally accepted dietary standards, methods of determining nutritional status which will permit comparison of one country with another, and simple methods for determining the prevalence of deficiency diseases will do much to lay a solid basis for international improvement in nutritional health.

Kwashiorkor is undoubtedly the most prevalent and serious nutritional deficiency disease in the world today. The committee has done much to gather and publicize the facts about this scourge. Rather simple methods are available for its prevention and cure, if they can be made known and applied. Beriberi continues to be a major problem in certain parts of the world. It too can be prevented and cured. Endemic goiter is still a major problem. Effective ways of iodizing locally produced salt would help combat this disease. The world population is still increasing faster than its food supply. Ways must be found to increase and extend the available food. The FAO/WHO Joint Expert Committee on Nutrition has and should continue to supply world leadership in meeting these problems.

JAMES M. HUNDLEY, M.D.,
National Institutes of Health, Public
Health Service

School Health Services

The Second World Health Assembly approved the inclusion of an Expert Committee on School Health in the WHO program for 1950.

The committee's task was to develop principles which would be useful in developing or extending school health services in all parts of the world where schools existed. These principles were to be as useful in underdeveloped areas as in areas more favored in their technical development. It was no small assignment. Fortunately for the committee, there was much help available from WHO sources. Members of the Secretariat of WHO brought their experiences to bear on our problems. Especially were we indebted to the divisions of nutrition, mental health, public health nursing, maternal and child health, and health education for their contributions.

Resource persons were found, too, in the WHO's maternal and child health regional advisers who had come to Geneva from the regional offices in Washington, D. C., Alexandria, Egypt, Hong Kong, and New

Delhi, India. These people, together with observers from UNESCO, ILO, and the Social Activities Division of the United Nations, supplied the committee with first-hand data and provided "criteria of applicability" by which the committee could judge the usefulness of its product.

The report as submitted to and approved by the Executive Board of WHO gave consideration to the following:

1. The reasons for asking for special attention to children in school; children's growth and developmental needs; opportunities for health instruction.

2. The broad aspects of a school health program which emphasizes cooperative planning, the inclusion of services, programs, and an environment which promotes the health of children. Definite guides for desirable emphases to be placed by physicians, nurses, dentists, teachers, and others in their work with and for children.

Three basic principles presented in the report are: (1) a program of

health for children can be conducted when only a teacher is available; (2) professional health staff, including physicians, nurses, and dentists, contribute additional services which enrich the health experiences of the child; (3) irrespective of the number and type of personnel available, a satisfactory educational program for the child can be developed only when there is an accepted philosophy of teamwork among the staff.

Other recommendations in the report emphasized the responsibilities and interrelationships of personnel serving children, their families, and the community. Suggestions were made, too, regarding the preparation of professional personnel as well as auxiliary helpers. Final sections presented statements relating to the administration of the school health program, and suggestions for future research.

DOROTHY B. NYSWANDER, Ph.D.,
Professor of Health Education, Uni-
versity of California

It is generally recognized that premature birth plays a major role in causing neonatal deaths. For this reason the Expert Group on Prematurity was convened in April 1950 to prepare for the World Health Organization recommendations for reducing premature infant mortality. The experts, who came from seven countries, represented the fields of obstetrics, pediatrics, and nursing.

First consideration was given to promotion and establishment of pertinent uniform definitions to provide for comparable vital statistics. The committee recommended that the international definition of prematurity of the First World Health Assembly be adopted by all countries and that the terms "abortion" and "stillbirth" be supplanted by the term "foetal death."

In considering programs to lower the incidence of prematurity, as well as the mortality from premature birth, the expert group pointed out that the initiation of a preventive program might well precede that of a specialized-care program. Named as prerequisites were the establishment of general public health measures and the strengthening of maternal and child health programs. Recommended content of a preven-

tive program included research into causes of premature birth; an educational program to acquaint pregnant women with the importance of early and adequate prenatal care; provision for prenatal services; adequate hospital facilities for women with complications of pregnancy; the enactment of legislation to protect the working woman; and provision for services to fulfill the requirements of such legislation.

In regard to the initiation of programs for care of premature infants the expert group named certain prerequisites such as accurate birth and death statistics; evidence of a downward trend in infant mortality; qualified medical and nursing personnel; adequate hospital facilities and equipment; and social services. The organization of the program should be related to the pattern of maternity care in a given country, that is, the proportion of births in hospital and at home. Under certain conditions a program might be initiated as a local demonstration before extension of the program to wider areas.

The minimum requirements outlined for establishing a hospital unit for premature infant care included qualified and experienced medical

and nursing staffs in adequate numbers; location of the unit in an area selected to minimize cross-infections; adequate space and special facilities; medical and nursing record forms. The importance of parent-teaching and follow-up were emphasized. In some areas, home care of prematures might be satisfactory if provision were made for hospitalization of sick infants and those of low birth weight. Certain requirements for a home-care program were specified.

The essentials for development of a complete program were outlined by the experts under four main headings: administration; medical, nursing, and social services; education of professional personnel and the public; and research.

Finally, the expert group urged the awarding of fellowships for study and research in problems of prematurity and recommended to WHO the development of an information service on all aspects of the problem of prematurity.

Research in Child Development,
Children's Bureau

Public Health Administration

The Expert Committee on Public Health Administration was authorized by the Third World Health Assembly in May 1950. The range of this committee encompasses the entire field of public health practice. This includes not only the content of organized programs, but also the organization, administration, financing, and staffing of health services.

Perhaps the best way to describe the work of this committee is to compare it with the other expert committees drawn from larger panels set up by WHO. Most of the expert committees were set up to focus international understanding and professional guidance on specific diseases, conditions, or standards. Their concern is with methodology,

with technical knowledge, and with scientific developments. The Committee on Public Health Administration is interested in all of these developments and programs as they become part of the armamentarium of organized health services. In other words, it is concerned with the organization, the resources, the facilities through which scientific knowledge is applied in the service of people.

In a sense, the work of this committee does not lend itself to ready classification or to finite results. Criteria and methods can be developed; techniques can be standardized, and the same kinds of knowledge or principles can be applied wherever the problem exists. But

actual services may reach people in a variety of ways, through many organizations, and through widely differing patterns of administration.

Thus, one of the first jobs of this committee is to gain a better understanding of problems of mutual interest and of the factors which complicate them. It may then address itself to fostering a rational approach to health administration suited to the needs of different countries of the world. The committee will determine, for example, where and how health might be improved through organized effort, and suggest measures applicable under different situations—geographic, economic, social, and cultural. One aim is to develop not specific blue-

prints but guidelines of successful practices based on the combined thinking and experience of representatives of many different nations and methods of operation.

It was in this frame of reference that the Expert Committee on Public Health Administration held its first session in November 1951. Specifically, the committee considered the activities that might be included in organized health programs, and lessons that have been learned from different types of local health organization and practice in various countries of the world. It attempted also to list and classify health services provided by official health agencies, to enumerate the health

functions at different levels of government, to show how the peoples of the world can participate in health work, and to outline some of the problems and needs of professional and technical personnel.

Obviously it was possible to consider these and similar problems only in a tentative and introductory fashion. Careful study is still needed in many fields—in the details of organizing and financing health programs, in the organization of health services in relation to socioeconomic and national background, in specific patterns to meet specific needs, to name only a few. Of particular importance is more thorough exploration of the problems in public health administration

encountered in the underdeveloped countries of the world.

The membership of this committee brings together a wide variety of experience in health administration. By acting as a resource and reference body for assembling and evaluating information and experience, by stimulating further study and exchange of knowledge, and by formulating general principles of desirable health administration and organization, it can play an important role in bringing us closer to world-wide health goals.

Chairman of the Department and
Professor of Public Health, Yale
University

Tuberculosis

The WHO Expert Committee on Tuberculosis has held five sessions since it was created in April 1947 at the third session of the Interim Commission.

At the first meeting in 1947, the committee discussed its fields of activity, techniques for the international control of tuberculosis, and emergency measures.

Because tuberculosis is epidemic in many countries, initial action was taken in applying emergency measures. The committee recommended that demonstration teams be formed to conduct intensive programs of BCG vaccination in war-devastated countries. Although the committee realized that this measure alone would not be sufficient to control tuberculosis in these countries, it hoped that this type of operation and its successful demonstration would encourage local groups to develop and conduct more comprehensive programs.

The BCG vaccination program has made vigorous progress with the

generous and energetic cooperation of the Scandinavian Red Cross Societies and UNICEF. Studies are also being made to determine the duration of immunity conferred by this vaccine and to establish more definitely its effectiveness as a preventive.

The more general fields of activity in international tuberculosis control were designated as prevention, case finding, isolation and medical care, rehabilitation and aftercare, and social and economic protection of afflicted families.

Among the techniques of control outlined by the committee were (1) determination of the extent of the problem; (2) recruitment and training of professional personnel; (3) provision for physical facilities, supplies, and equipment; (4) public health education; (5) field services in administration, epidemiology, laboratory, and clinical work; (6) the provision for adequate funds; and (7) the development and establishment of uniform procedures in:

tuberculin and tubereulin testing, preparation and clinical use of BCG, classification of tuberculosis, X-ray interpretation and mass radiography, laboratory diagnosis of tubercle bacilli, and evaluation of new chemotherapeutic agents.

It also suggested the establishment of cooperative working relationships with all official and voluntary groups actively engaged in some aspect of tuberculosis control; eradication of tuberculosis in cattle; counsel to national governments and health departments on sound laws and regulations pertaining to human and bovine tuberculosis; and review and evaluation of the program at regular intervals.

During 1950, the expert committee was enlarged and reconstituted as a panel of experts in tuberculosis, to be consulted from time to time as new problems arise.

HERMAN E. HILLEBOE, M.D.,
Commissioner, New York State
Department of Health

For purposes of brevity, names of committee members and other facts have been omitted from these statements. Full reports of the committees, however, are published in the World Health Organization's "Technical Reports Series." These and other publications of WHO are available through the Columbia University Press, International Documents Service, 2960 Broadway, New York, 27, N. Y. Orders may also be addressed to: World Health Organization, Sales Section, Palais des Nations, Geneva, Switzerland.

WHO and Environmental Health

By HERBERT BOSCH, M.P.H.

"More than three-fourths of the world's population drink unsafe water, dispose of their human wastes recklessly, prepare their milk and food dangerously, and are plagued by insects and rodents." An even more startling statement on the magnitude of the problem of faulty environment is that of the Director-General of the World Health Organization, "one-fifth of all the deaths in the world are due to faulty environment" (1). Yet quoting Dr. H. Van Zile Hyde, "The major health problem of the world today is not death—it is chronic and repeated infections and infestations which convert man from a productive unit of society to a liability to society" (2). It is small wonder, then, that the World Health Organization is devoting more and more attention to problems of environmental health. The WHO proposed program and budget estimates for the year 1952 state:

The ravages of water-borne, insect-carried and excreta-transmitted diseases outweigh in economic and public health importance those of almost any other group of diseases. Their control is based on universally accepted principles of sanitation and hygiene. Their origins are nondebatable; their epidemiology has long been known; the costs of correction, although significant, are often not insuperable if ingenuity and imagination are applied. With the limited funds at

Professor Bosch was chief of the environmental sanitation section of the World Health Organization, 1950-51. He is now professor of public health engineering in the University of Minnesota School of Public Health. His extensive experience has included Army service here and in Europe and sanitary engineering assignments with the State health departments of Missouri and Minnesota.

its disposal WHO will continue to assist member states in improving environmental sanitation, for it is evident that this is work which will yield very large returns.

Many observers at the Fourth World Health Assembly, which met in Geneva in May 1951, commented on the increasing interest in environmental sanitation shown by the delegations from nearly all member states. Illustrative of this spirit was the resolution introduced by the Indian delegation and unanimously adopted by the Assembly. It urged member states to employ more sanitation personnel and recommended that WHO help in the creation of training facilities for such personnel. Col. M. Jafar, the principal delegate for Pakistan, and chairman of the program committee of the Fourth World Health Assembly, said that the committee was of the opinion that the best way of proving the importance of preventive medicine was to choose projects which give demonstrable results and that environmental sanitation projects were particularly suitable from this standpoint. It is also significant that the theme of the 1952 World Health Day was "Healthful surroundings make healthy people."

Organization of Sanitation Services

In the Secretariat of the World Health Organization the division of environmental sanitation on January 1, 1952, was charged with responsibility in the following fields:

1. Municipal sanitation, including water supplies, sewage and waste treatment, garbage and waste disposal.
2. Rural sanitation, including water supplies, sewage and excreta disposal, sanitation of isolated dwellings.
3. Housing and town planning.

4. Insect, rodent, and other vector control (acting as a service unit to the medical divisions and sections having responsibilities in this field).

5. Milk and food sanitation.

6. Environmental phases of occupational health.

7. Advice to the division of education and training on matters pertaining to environmental sanitation personnel.

The director of this division participates with the directors of the other eight technical and three administrative divisions in the Secretariat on over-all planning and coordination. Not all of the environmental health activities of WHO are conducted by this division. For instance, the work in malaria control, which has been an outstanding example of effective preventive medicine, is a responsibility of the malaria section, a component of the division of communicable diseases. There is, however, in the WHO Secretariat a general desire to eliminate water-tight compartments, and there has been close cooperation between the personnel assigned to the malaria section and those in the environmental sanitation unit.

Operational responsibility for environmental sanitation activities is vested in six regional offices serving: Africa, the Americas (the Pan American Sanitary Bureau serves as the regional office for the Americas), Southeast Asia, Europe, Eastern Mediterranean, and the Western Pacific.

The staff of each of these regional offices includes an adviser on environmental sanitation who is a sanitary engineer with public health experience and training. Usually, there is also a regional adviser on malaria. WHO demonstration teams, consultants, and personnel conducting other activities in individual member states are under the supervision of the appropriate regional office. WHO does not have legal authority over any member states—it operates only at the request of the nation affected. In appropriate fields work is done cooperatively with the other specialized agencies of the United Nations such as the Food and Agriculture Organization, the United Nations Educational, Scientific, and Cultural Organization, the International Labor Organization, and the United Nations International Children's Emergency Fund. Every attempt is also made to utilize the resources of the United Nations

Water treatment plant at AKABA Refugee Camp near Jericho (Hashemite Kingdom of Jordan). Operator is an Arab refugee. The T 3 GD8 on the building indicates that it has received a DDT, ganexane residual spray.

program for technical assistance for economic development of underdeveloped countries.

Methods of Operation

The very small budget, considering the number of activities attempted, allows WHO to assign only a limited number of personnel to environmental sanitation work. On December 1, 1951, less than 75 persons, including physicians, entomologists, public health engineers, and sanitarians, were assigned to such activities. Ten of these were on teams assigned to relief operations among the civilians of Korea. It is therefore apparent that WHO cannot make a significant impression on sanitation problems by attempting to intensify and augment the work of existing national agencies. To have an appreciable effect, WHO has directed its efforts principally toward such activities as:

1. Collection and exchange of scientific and technical knowledge by expert committees, expert panels, and scientific conferences.
2. Training of national personnel by assignment of demonstration teams.
3. Training either by traveling fellowships or by enrollment in formal academic courses.
4. Strengthening of training facilities.
5. Short-term expert consultation on specific problems.

The results obtained by these methods when compared with the expenditures have been ex-

ceedingly good. Most of the work has been sound and will have long-time effects.

Expert Panels and Committees

Expert panels and expert committees on various specific subjects are widely used by WHO. Members of the various expert panels are selected by the Director-General because of their knowledge in specific fields and with regard to geographic distribution. Before making an appointment to a panel, the Director-General obtains the concurrence of the government of the country of which the expert is a citizen. However, that government does not nominate candidates for the panel. Hence, expert panel members do not officially represent their countries. The members of these panels are expected to keep the Secretariat of WHO advised of current developments in their specific fields and areas. They also receive information furnished by other members of the panel.

From the expert panels, the Director-General from time to time constitutes expert committees which are convened to advise WHO on the technical aspects of its activities. The reports of the committees are published in a WHO Technical Report Series and are available at very low costs from agents in most countries. To persons interested in environmental sanitation, the reports of the Expert Committees on Environmental Sanitation, Malaria, Insecticides, and Cholera are particularly valuable. These reports represent the consensus of well-recognized experts. The reports of the committees are transmitted by WHO to all of its member states. The Executive Board of WHO may comment on the reports but it does not amend them.

Conferences and Seminars

Another device for exchanging scientific information has been the use of conferences and seminars. In Europe two conferences on sanitary engineering have been held. The first in 1950 at The Hague was conducted under the auspices of the Government of the Netherlands, WHO, and the Rockefeller Foundation. Representatives from 14 European nations were present. The primary objectives of the con-

ference were: (a) to disseminate knowledge of the status and needs of sanitary engineering in the various countries; (b) to stimulate and coordinate European research in environmental sanitation; (c) to bring about closer relationships between sanitary engineers in the countries of Europe.

The conference was highly successful from the standpoints of exchange of information and of focusing attention on the need for coordination of research. There is no doubt that the third objective was also accomplished. The Rockefeller Foundation, the Government of Italy, and WHO conducted a similar conference in Rome in November 1951. In addition to engineers, a number of physicians from national health departments attended. From the conference the public health administrators learned more about the contributions the engineer can make to the public health team.

Another outstanding conference sponsored by WHO (in conjunction with the Commission for Technical Cooperation in Africa South of the Sahara) was the Malaria Conference held in Kampala, Uganda, in November and December 1950. This conference, participated in by well-known experts, considered all available information and made specific recommendations for malaria control work.

Demonstration Teams

Teams of specialists sent to individual countries have been used by WHO to train personnel in that country in new techniques. In the environmental sanitation field most of these specialist teams have been concerned with malaria control. Teams for mosquito and other insect control have functioned in four different areas in India, and in Pakistan, Thailand, Afghanistan, and Cambodia. Iran and six countries of Central America have also been assisted in insect control work. Frequently such teams must first obtain information on the mosquito vectors in the area and then must develop economical methods of control. The work done by these malaria control teams has been highly beneficial. There is no doubt that they are truly demonstration teams. Dr. Leonard A. Scheele, president of the Fourth World Health Assembly, in his presidential address, made the

statement that the WHO malaria control teams had protected directly only 1½ millions of people but that the demonstrations of these teams had resulted in programs which are protecting 50 million people. These malaria control teams have included in their personnel either public health engineers or sanitarians. These sanitation personnel have done much general sanitation work in addition to malaria control. Several countries, including Pakistan and Afghanistan, strongly requested the continuation of general sanitation activities after the malaria control teams finished their assignments.

A contemplated type of WHO specialist team activity is the use of cholera control teams, each of which will have a public health engineer as an important member. The WHO Expert Committee on Cholera, meeting in New Delhi in November 1951, recommended that sanitation measures be one of the principal methods of attacking cholera. The arguments for this were skillfully put forth in a paper prepared by K. Subrahmanyam (3), professor of sanitary engineering at the All-India Institute of Hygiene and Public Health. One pertinent portion of his paper follows:

The fact that we know about cholera is that it can be transmitted from person to person through drinking water or food contaminated with the organisms. This is sufficient to justify a demand for uncontaminated water and food, and an environment in which there will be few flies and no excreta exposed or accessible to flies. The demand is for environmental sanitation, and when that is granted it should reduce the chances of spread of the disease, reasoning on the facts we know. Environmental sanitation appears to be a necessary condition for eradication of cholera.

A type of demonstration team which is coming more and more into use in WHO is the general public health team. These teams always include a public health engineer or a sanitarian. This fits into the concept that to develop public health protection in most countries there is a need for a program that includes all the basic services, of which one certainly is environmental sanitation.

Training Personnel

Specialists and experts from other countries can be, and are, a great help to an underdeveloped country in starting a program. However,

Arab refugee in the Hashemite Kingdom of Jordan performing orthotoluidine test for residual chlorine. He was trained by a WHO engineer.

to make a sound environmental sanitation program stick, the leaders of the program must be nationals of the country and must have the specialized training necessary to carry on the program. The sanitation personnel in these countries must be at several levels of competence. The second meeting of the WHO Expert Committee on Environmental Sanitation devoted its entire time to the questions of the education, training, and utilization of sanitation personnel. The following statement in the committee's report is relevant to the use of high-level personnel in underdeveloped countries:

The assumption, perhaps too widely made, that underdeveloped regions are not prepared for the services of the best trained specialists in environmental sanitation can readily be contested. Countries of minimum resources are most in need of the highest expert service available, both for diagnosis of need and for programing of solutions. The relegation of these functions to less adequately prepared persons results from a great misunderstanding of the complexity of the problems in environmental sanitation normally encountered in areas of low economic level. These

problems require for their solution the impact of high intelligence, training, and experience, even when the number of persons possessing such qualifications is necessarily a minimum. It is unsound practice literally to send a boy to do a man's job.

WHO Fellowships

To assist in training top sanitation personnel both in governmental work and in teaching positions, WHO grants fellowships which finance the cost of the training of individuals selected by their government in consultations with WHO officials. Some training fellowships are used at established educational institutions. In other cases the grant is for a traveling fellowship which the fellow uses to visit and to make observations on installations, governmental units, institutions, and other places or programs of particular interest to him. Ordinarily these traveling fellowships are reserved for persons who have had sufficient experience to allow them to evaluate their observations and to adapt them to their own conditions. A number of United States citizens have received such fellowships—a typical one was granted the sanitary engineer of the Alaska Health Department to allow him to study cold weather sanitation practices in the northern Scandinavian countries. Another grant allowed the chief sanitary engineer of the Ministry of Health of Israel to observe sanitation practices in the Americas.

Fellowships for formal study at educational institutions are widely used. The purpose of the fellowships, of course, is to train key people who will be able to develop and improve programs in their own countries. For instance, a fellowship was granted in 1950 to an engineer from the Hashemite Kingdom of Jordan for studying sanitary and public health engineering at the Imperial College of Science and Technology (London) and the London School of Hygiene and Tropical Medicine. This engineer is now in the governmental service in his country and is the first sanitary engineer to be so employed. Only in exceptional cases are fellowships for formal education granted to undergraduates—WHO feels that the candidate should have had his basic training before he receives financial assistance. One exception to this rule was the granting of a fellowship to an undergraduate engineer from Liberia. In that

country only one national has an engineering degree, and there is no university or school offering engineering education. It was the belief of WHO officials that one of the basic needs was for a sanitary engineer in the Health and Sanitation Department of the Republic and that the fastest method of fulfilling this need was to assist in the training of a suitable candidate at the undergraduate level.

In many of the underdeveloped countries, there is a great need for the training of intermediate and low-level sanitation personnel. Obviously, such training must be given locally. Within the limitations of its budget, WHO attempts to assist in such training. In the African region a sanitarian, experienced in tropical sanitation, devotes much of his time to this type of activity. In Afghanistan, the WHO sanitary engineer spends a large portion of his time in such training work.

Strengthening of Training Facilities

The prevailing feeling in WHO is that, in general, sanitary engineers and other sanitation personnel profit more if their first formal specialized training is received in a locality where the climatic, economic, and cultural patterns are similar to those in their own country. If this is to be done, strengthening of training facilities in the underdeveloped countries is essential. Unfortunately, WHO's budgetary provisions for such action are limited. However, some assistance has been given toward the strengthening of sanitary engineering work at the All-India Institute of Hygiene and Public Health by a grant for the purchase of equipment, and a current project provides for a professor of sanitary engineering for Thailand.

Short-Time Consultants

WHO furnishes a considerable amount of assistance to its member states by the use of short-time consultants. Such consultantships in specific problems frequently make it possible to obtain experts who would not be available for long-time employment. These services are requested at times by the highly developed countries as well as by countries which have not progressed so far economically. For instance,

consultants have not only gone from the United States, but the program also operated in reverse when an expert on garbage and refuse disposal from the United Kingdom gave assistance to Federal, State, and local health authorities in the United States.

Services for Special Groups

Earlier in this discussion it was implied that WHO does not conduct routine operational programs. There is an exception to this rule since the constitution of WHO states that WHO shall "provide or assist in providing, upon the request of the United Nations, health services and facilities to special groups." Two large special groups, the civilian population of Korea and the Arab Palestine refugees, have been furnished health services.

In Korea, WHO was asked in 1950 to furnish personnel, including 10 sanitation specialists, to serve under the unified command. Five sanitarians and 5 sanitary engineers were recruited to bring emergency health services to the hordes of civilians whose lives were disrupted by the war. Their work was concentrated on matters of basic sanitation and insect control. On January 1, 1952, all health and sanitation work of the United Nations was taken over by the United Nations Korean Reconstruction Agency and these personnel were given the option of transferring to the new agency.

In the Near East, WHO had also assisted in carrying on a health program among the Arab Palestine refugees. These refugees now live in areas of Lebanon, Syria, Hashemite Kingdom of Jordan, and the Gaza area. The over-all United Nations responsibility is vested in the United Nations Relief and Works Agency for Palestine Refugees in the Near East.

The health and sanitation staffs were partially recruited by WHO, and the work is headed by a public health physician employed by WHO. Two of his principal staff members are also WHO employees—a physician-malariologist and a sanitary engineer. The environmental sanitation work among these refugees has been of prime importance since more than half of the 800,000 refugees are living in crude hut and tent camps in a highly malarious region. In many cases there was a problem not only of providing satisfactory sanitary facilities but also of educating the inhabitants of the camps in proper methods of use. A problem of great magnitude is that of fly control since flies in that area are not only implicated in the transmission of gastrointestinal diseases but are also the cause of many of the ophthalmic conditions observed in children. The fly problem certainly has not been solved, but it has been reduced.

Conclusion

Because of limitation of funds WHO has made only a meager beginning on many of the sanitation problems of the world. However, its environmental control work has been sound. With a more adequate budget WHO could accelerate the progress which its individual member states are making in producing a satisfactory physical environment.

Bacterial Genetics and Drug Resistance

By BERNARD D. DAVIS, M.D.

The emergence of drug-resistant organisms in patients receiving chemotherapy has presented a serious medical and epidemiological problem. To a certain extent this problem is abating; for although most organisms readily develop significant degrees of resistance to sulfonamides or streptomycin, there has been little clinical appearance of resistance to penicillin, except among staphylococci, or to the newer antibiotics (chloramphenicol, aureomycin, and terramycin). In the treatment of tuberculosis with streptomycin, however, drug resistance remains a major limitation.

This problem in tuberculosis has been discussed in detail by Yegian and Vanderlinde (1). The present paper will particularly consider drug resistance in the light of developments in bacterial genetics.

Bacterial Variations

In this recently expanding discipline, bacterial variations, long studied by bacteriologists in an empirical manner, have been re-examined from the point of view of modern genetics (2). With few exceptions, these variations have been found to fall into two classes: physiological and genetic. Physiological adaptations to a changed environment involve all the cells in a culture, and are noninheritable, being reversed by return to the original environment; genetic changes, in contrast, involve only a tiny fraction of the cells in the original population, and

are inheritable, being transmitted from generation to generation of the offspring of the changed cells, even when grown in the original environment. Drug resistance belongs to the inheritable class, which also includes inheritable changes in a variety of other characteristics, such as morphology, nutritional requirements, and virulence.

Inheritable bacterial variations resemble the mutations of higher organisms, as Beijerinck pointed out within a few months after the discovery of the latter by De Vries in 1900. Only within the past decade, however, has it become generally recognized that the two processes are alike in several respects: not only are their effects inheritable, but both changes occur spontaneously in an exceedingly small fraction of a population of cells, and both are increased in frequency by certain physical agents (ultraviolet, X, or radioactive irradiation) or certain chemicals (e. g., nitrogen mustards). The resemblance is further emphasized by recent evidence that bacteria have much the same genetic apparatus as do cells of higher forms: nuclei have been demonstrated in bacteria (3), and within these nuclei there are chromosomes which appear to undergo mitosis (4). Furthermore, some bacterial strains can inherit features (including acquired drug resistance) from two different parents, as in the sexual process of higher organisms (5). Let us, therefore, briefly consider the nature of genetic mutations. A stimulating exposition of genetic principles can be found in Schrödinger (6).

Mutations

By many lines of evidence it has been shown that almost all the inherited properties of ani-

Dr. Davis is a senior surgeon, Public Health Service, assigned to the tuberculosis research laboratory at Cornell University Medical College, New York City.

imals or plants are transmitted by their genes—self-duplicating material units or regions located in chromosomes in the nuclei. The inborn nature of an organism is determined by the combination of genes it receives from its parents. Usually each individual gene is transmitted unchanged from generation to generation, but rarely—with most genes, once in a million to a billion cell generations—a gene will spontaneously undergo an inheritable change. These changes are called mutations; a cell or organism bearing a mutated gene is called a mutant. Mutations occur at random; it is impossible to predict which individual in a population, or which gene in an individual, will undergo mutation in a given generation.

These spontaneous mutations, along with Darwinian natural selection, are considered by modern geneticists to be the mechanism of evolution in the biological kingdom. Mutations of all sorts are constantly occurring in all species; each environment selects for survival those mutants that are especially fitted for that environment. Even in the nineteenth century, before the discovery of mutations, biologists had largely abandoned the alternative Lamarckian view that organisms can inherit characteristics acquired by a specific useful or purposive adaptation to the environment. All experimental attempts to demonstrate such a process failed.

It should be emphasized, however, that the nineteenth-century experiments that defeated Lamarckism involved only characteristics (e. g., mutilations) acquired by somatic cells. And, indeed, one could not conceive, in terms of modern biology, that a giraffe's neck stretched or a puppy's tail hacked by an experimenter could lead to a longer neck or a shorter tail in the next generation. The hereditary nature of this generation would be determined by the parents' germ cells—the spermatozoa and ova—and these have no evident means of reflecting a mechanical change in the somatic cells.

But is it safe to exclude the Lamarckian theory for one-celled species as well as for higher organisms? In bacteria there is no distinction between germ cell and somatic cell; there are only genetic (heredity-determining) and nongenetic parts of a single cell. It is therefore conceivable that a drug, having penetrated into a bacterial cell, might somehow

direct changes in the genetic part of the cell that would result in a mutation to drug resistance. To be sure, the fact that resistance arises only in a tiny fraction of the population might seem to suggest a spontaneous origin of the mutation, but it hardly proves such an origin—for the very test for the presence of these resistant cells in the population always requires exposure of the population to the drug, and it might be *during* that exposure that the mutation first occurs. Neither the nineteenth-century polemics on evolution nor careful scrutiny of the ordinary drug experiments can settle the issue; a subtler approach is needed.

Evidence for Spontaneous Mutations

The question was answered definitely by a statistical approach (fluctuation analysis) designed by Luria and Delbrück (7) to study the similar problem presented by bacteriophage resistance and subsequently applied by Demerec (8) to drug resistance. The argument runs as follows: Let a few colon bacilli, including no drug-resistant mutants, be inoculated into a flask containing 100 ml. of medium, and at the same time inoculate a few bacilli into 100 tubes each containing 1 ml. of medium. After incubation, the total number of bacteria in the 100 small vessels is the same as the number in the large one. And if the contents of the 100 small vessels are mixed, and samples from this mixture and from the original flask are tested by plating in the presence of the drug, the number of resistant mutants is also found to be about the same in the two lots of bacteria.

But if the 100 tubes, instead of being mixed, are separately tested, what will the distribution be? There are two possibilities. If the mutations do not occur until exposure to the drug, these separately grown samples should be indistinguishable from 100 samples from the single flask and should show the same distribution as is found with the latter, namely, a constant number of mutants in each sample, except for the inevitable statistical variation in sampling. But if the mutations have occurred before the test with the drug, the numbers of mutants in the 100 tubes should fluctuate more widely, for the following reasons. Since mutations are chance events, some tubes will develop a first

Back-Pressure Arm-Lift Artificial Respiration

By HEINZ SPECHT, Ph.D.

On December 6, 1951, the Department of Defense announced the adoption of an improved method of manual artificial respiration. The new method, a back-pressure arm-lift method originally described by Holger-Neilsen, has been adopted by other organizations, including the American National Red Cross; the American Telephone and Telegraph Co.; United States Bureau of Mines; Boy Scouts of America; Camp Fire Girls, Inc.; Council on Physical Medicine and Rehabilitation, American Medical Association; Federal Civil Defense Administration; Girl Scouts of the U. S. A., Inc.; and Public Health Service, FSA.

. . .

Opinions regarding the "best" method of manual resuscitation have never been unanimous. Until 1927, when the Public Health Service Conference on Artificial Respiration was held, a variety of methods were used. As a result of that meeting, a number of groups (1) representing the major interests in this country agreed that the prone-pressure method be adopted as the standard to be taught throughout the country.

Sporadic interest in the basic principles of resuscitation continued in the laboratories, but their findings rarely reached the groups teaching resuscitation methods. The general feeling that manual resuscitation was only par-

tially successful stimulated efforts to develop mechanical aids. Some authorities still consider that the manual method is only a temporary measure to be used until mechanical means can be applied, whereas it is evident from the recent research that proper manual methods are fully adequate.

Analyses of the effectiveness of manual methods on the basis of field experience have not been reliable, for obvious reasons, and the most optimistic reports indicate that not more than 75 percent of the efforts at manual resuscitation were successful. It is apparent that an accurate estimate of the ratio of successful to unsuccessful resuscitation attempts cannot be made. Unsuccessful cases are not likely to be reported, and reports of successful attempts include persons who would have revived without application of artificial respiration.

It was the realization of this general feeling, at least among the medically and scientifically trained portion of the population, that led the Red Cross in 1946 to support specific investigations on the effectiveness of various methods of manual artificial respiration. In 1948, a conference on this subject, called by the American National Red Cross with a subcommittee of the Committee on Physical Medicine of the American Medical Association, increased the impetus to apply modern methods of quantitative research to the problem. In 1949, the medical laboratories of the Army Chemical Center took up the question in connection with chemical warfare.

The import of these discussions, especially as they bore on civil defense activities, brought the whole matter to a critical point. Rapid progress was made when, in 1950-51, the several military departments supported four decisive

Dr. Specht is a physiologist who has done a great deal of work in the field of respiratory physiology. He is with the National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, Public Health Service, Bethesda, Md.

Back-Pressure Arm-Lift Artificial Respiration

Correct positions for the back-pressure arm-lift method of artificial respiration are illustrated below. In this method the person is placed prone with the elbows bent and with one hand upon the other. The forehead is placed on the hand with the face turned slightly to one side. The operator kneels on one knee at the head of the victim.

1 To start the cycle the operator places his hands on the victim's back so that the thumbs just touch and the heels of the hands are just below a line between the armpits.

2 He then rocks forward slowly, keeping the elbows straight, until his arms are approximately vertical, exerting steady pressure upon the back.

3 Then he rocks backward, slowly sliding his hands to the victim's arms just above the elbows.

4 Continuing to rock backward he raises the arms to lift the chest weight from the floor and expand the chest.

investigations in response to the need for conclusive data to support the most effective method for inclusion in the pending revisions of the military first-aid manuals. On October 1-2, 1951, the National Research Council's ad hoc committee on artificial respiration recommended that the Holger-Neilsen method be adopted as the standard method of manual artificial respiration. This recommendation was based on a series of investigations (2-7) which should be understood by all public health workers. Although many national organizations teach resuscitation, and it is the direct function of the American National Red Cross to teach the newly selected standard method for the civil defense program, the dissemination of the reasons for the change from the Schafer prone-pressure method should be undertaken by every person in a position to use, teach, or recommend resuscitation procedures.

The several investigations (2-7) form the most significant assay of manual artificial respiration that has been attempted.

Resuscitation Methods

Actually, many variations of several basic methods were applied, but in general it was found useful to categorize the methods functionally as to what is done to the subject and to observe the most effective technique for each of a selected group. These are briefly defined as follows:

Prone Pressure (Schafer). Subject on belly, head on hands, mouth to side, bimanual pressure applied to lumbar back.

Supine Chest-Pressure Arm-Lift (Silvester). Subject on back, mouth up or to side, operator folds forearms over chest applying pressure, unfolds arms and extends them over subject's head, either partly or completely horizontal.

Prone Back-Pressure Arm-Lift (Holger-Nielsen). Subject on belly, head on hands, mouth to side, operator applies bimanual pressure below shoulder blades, then lifts arms at elbows to expand rib cage and partially lift chest.

Prone Hip-Lift (Thompson, Emerson-Ivy). Subject on belly, head on hands, mouth to

side, operator raises hips 4 to 6 inches. (May be combined with back pressure.)

Prone Hip-Roll (Emerson-Ivy). Subject on belly, head on hands, mouth to side, operator raises one hip 4 to 6 inches. (May be combined with back pressure.)

The principal difference between the prone-pressure method and the others listed is that the latter include an active inspiratory maneuver either by manipulation of the arms or by raising the hips. This action affords not only greater tidal exchange but also, perhaps, a larger surface for gaseous exchange.

One of the more important advances in methods of study of manual artificial respiration lies in the use of curarized and anesthetized volunteers (2) whose flaccid condition simulates the deep asphyxial condition of the more serious apneic cases. In addition to this, large numbers of acapnic apneic volunteers, some traumatic apneics, and large numbers of fresh cadavers were also subjected to the various artificial respiration methods. The various approaches gave essentially similar results (2-7) which will be briefly paraphrased here.

Results of Studies

The studies on air-flow patterns and pulmonary ventilation (2) show that the two-phase methods as a group are about twice as effective as the prone-pressure method. Pneumotachographic analysis shows that a rate of 10-12 complete cycles per minute in these cases permits completion of each cycle.

Pulmonary ventilation studies on nonapneic subjects (3) gave results similar to those on apneic subjects, indicating an equivalence of the various two-phase methods and a twofold superiority over the prone-pressure method.

Studies on the mechanics of breathing during artificial respiration by the various methods (6) showed that the two-phase techniques were superior to the prone-pressure method in clinical traumatic apneics and that air-flow measurements indicated a better utilization of the respiratory cycle for ventilation in the two-phase techniques than in the prone-pressure method. A similar experience regarding the efficacy of the various methods (7) was reported from another group of clinical apneics in which

higher rates of respiration were found to be more effective.

Circulatory studies (2) showed that the prone-pressure method could not maintain adequate blood oxygen levels in three of nine cases and that it gave the lowest blood oxygen levels of any method used. All the two-phase methods gave adequate blood oxygen values, although none produced normal saturations. Hyperventilation was not found to be deleterious in these subjects.

The energy expended by the operator in carrying out the various maneuvers was assessed in terms of oxygen consumed per unit time (2,4). It was apparent that the prone-pressure maneuver was least taxing, the hip-lift method most taxing, and the others intermediate.

The "teachability" of the previously non-standard methods (5) was assessed on a large group of operators (667 male and 214 female). Both objective and subjective reports indicated that a 10-minute instruction period was sufficient to adequately teach the various back-pressure hip-lift maneuvers. The back-pressure arm-lift method was found to be more readily learned than the hip-lift maneuvers. The principal difficulty leading to variation in learning and execution lies in the difference in size between the operator and the subject.

Together with the background of earlier work these data indicate that the prone-pressure method (a) produces the least pulmonary air exchange of the major methods that have been proposed; (b) that in some individuals the air exchange is no greater than the volume of air in the respiratory passages; and (c) that it is less effective in flaccid individuals, that is, as occurs in deep asphyxia.

Although nearly all methods in the hands of unskilled or unthinking operators may produce trauma, especially where damage exists, there are no such reports from countries where the back-pressure arm-lift method is practiced

generally. On the other hand, the prone-pressure method has been reported to have caused occasional trauma principally in the hands of large operators on slight or immature victims. Obviously, discretion must be used when traumatic accident cases are handled. For this reason alternative methods should be available. From the several two-phase methods, such a choice can readily be made without serious loss of ventilating efficiency.

It is apparent that the back-pressure arm-lift (Holger-Nielsen) maneuver is the choice for a standard manual artificial respiration method, on the basis of efficiency, ease of teaching, and feasibility.

Effect of Incomplete Information on Estimating Prevalence of Disease

By ALBERT P. ISKRANT, M.A., and QUENTIN R. REMEIN, B.A.

One of the most difficult problems for the statistician who is attempting to measure the incidence or prevalence of abnormal physical conditions in groups or samples of persons is the effect on his estimates of the "not observed"—the nonrespondents in the sample group to be studied.

This problem occurs in many fields of investigation. The statistician may wish to estimate the prevalence of syphilis in males of certain age groups, on the basis of the results of blood tests made as part of their selective service examinations. How about persons deferred for nonmedical reasons, volunteers, or those rejected for physical reasons before being blood tested? Does the omission of blood-test results on these persons bias the estimate and vitiate our generalizations?

Perhaps an estimate is needed of the prevalence of certain diseases in a community, based on the results of a screening examination—a mass blood-testing, mass X-ray, or multiple screening program. Will the nonrespondents show the same results as those who are examined—the volunteers or those examined as members of groups (as in industrial programs)?

Mr. Iskrant, chief of program analysis in the Division of Chronic Disease and Tuberculosis, Public Health Service, was formerly a statistician in the Division of Venereal Disease. Mr. Remein is a statistician in the latter division. This paper was presented at the annual meeting of the American Public Health Association and the Biometrics Society, November 1; 1951.

Do those who know they have the disease in question stay away from the clinic or come in for a check-up? Even if a population sample is obtained, what is the effect on the survey results of those who will not allow themselves to be examined because they know they have the disease, don't want to "know for sure," or are ill from other causes? And even if they do allow themselves to be examined, when an attempt is made to make findings of the screening survey more specific by securing diagnoses on suspects, what is the effect of the physician's hesitancy to make a diagnosis or his unwillingness to report it? Is the physician more or less willing to report a diagnosis if he knows that the person being screened has previously been diagnosed as having the condition which is being studied?

Another area in which lack of information about part of a group may influence results is in investigations of the effectiveness of a particular type of treatment on a selected group of persons. In this group will be some patients for whom post-treatment observation is not complete because of the patient's unwillingness to be examined, because he moved out of the area of the study, or because of death from other or unknown causes.

We have used data from the Richmond, Va., and Atlanta, Ga., multiple screening projects, from the Mississippi blood-testing projects, and from a special follow-up study of the Division of Venereal Disease to analyze the effect of nonresponse of patients on prevalence estimates and also on case finding and evaluation of treatment.

Richmond Project

The Richmond multiple screening project was designed to discover syphilis and other diseases detectable by blood testing and other diagnostic methods, and to educate the public regarding these conditions. Suspects—persons screening above or below specified levels or with abnormal readings—were referred to physicians, who were asked to report their diagnoses to the health department on forms provided for the purpose. To evaluate the effectiveness of this project as a case-finding program and to estimate the prevalence of certain diseases in the Richmond population, information was needed on (a) who responded to the appeal and who did not and (b) whether physicians examined all suspects and reported the results of all examinations to the health department or whether the recorded results were biased.

The Richmond multiple screening survey was intended to reach persons 15 years of age and over. Of the total 37,609 persons who were screened, 37,498 were known to be 15 years old or over, of known sex, and either Negro or white. Comparison of the respondents in the survey with the 1950 census of Richmond showed that the survey population had a more than proportionate share of white females, and therefore was not in proportion to the census as to race and sex.

About one-fourth of the white female respondents, all aged 25 to 34, were tested, whereas examinations were made of only one-seventh of the total population of the city. Negroes, both male and female, were poorly represented in all age groups. The young and the old of both races did not participate as well as did the middle-aged.

If the prevalence of diseases were related only to sex, race, and age, the findings for each group in the survey could be expanded to the total population of Richmond. But perhaps prevalence of disease is in part dependent on socioeconomic status or on quality of disease prevention or medical care, which also may be based on socioeconomic status. Education is usually considered a good index of this status, and records were available for persons tested in Richmond.

Persons going through the screening line were

questioned regarding their education. Data on schooling from the 1950 census for Richmond are not yet available but, unless there has been a great change since 1940, it would appear that the screenees are better educated than the general population of the city. This is true for all four race-sex groups. Although the population of Richmond in 1950, by sex, race, age, and schooling, is not the same as in 1940, the percentages of 1940 groups going through the screening line are presented in table 1. While these percentages obviously are not valid for 1950, their relationship may be. The group with the highest representation in the screening line was composed of Negro female college graduates, followed by white female college graduates. Next came white females with 1 to 3 years of college, and then Negro male college graduates. The white college man was the poorest in attendance of all the college groups.

Table 1. Percent of 1940 population over 25 years of age going through screening line, by years of school completed, race, and sex, Richmond, Va., January-July 1950

School years completed	White		Negro	
	Male	Female	Male	Female
None.....	1.5	2.5	1.8	0.7
Grade school:				
1-4.....	10.7	11.6	7.0	3.4
5-6.....	11.6	18.2	8.7	5.8
7-8.....	13.2	26.4	16.0	11.7
High school:				
1-3.....	19.0	39.8	22.8	19.6
4.....	32.5	57.2	33.3	33.4
College:				
1-3.....	36.4	62.6	54.1	43.0
4.....	35.7	67.2	58.2	76.4
Total college.....	36.0	64.3	56.2	54.7
Not reported.....	43.0	64.1	63.5	48.7
Total.....	21.4	41.2	13.2	11.7

In each group studied, more white females attended the clinic than white males. In each group other than college graduates, the white female attended better than the Negro female. In all but two groups (high school and college graduates), the Negro male attended better than the Negro female, and, in all groups above the high school level, the Negro male attended better than the white male. For all sex-race groups, increase in attendance was associated with increase in education. Thus, the poor at-

tendance of Negroes at all ages may be a result of lack of education. Obviously, then, no generalizations for the entire population of Richmond can be made from results of the screening survey, since the attendance of respondents was biased in favor of whites, females, and the better educated.

Other characteristics of the respondents and nonrespondents in Richmond not revealed by the survey records are reported by the Health Information Foundation, which conducted an analysis of the multitest clinic (1). The foundation reports that the respondents usually come from the middle-income group rather than from the high- or the low-income group, from households with a low average number of persons, and from households where some member is covered by health insurance.

The next problem considered was the non-response or incomplete diagnosis by physicians, due either to the screenee's unwillingness to visit the physician or to the physician's hesitancy to report his findings. Physicians whose surnames began with the letter B were chosen as a sample, and the forms for all persons who had been referred to these physicians were withdrawn from the files. There were 93 physicians in this group, to whom 1,102 suspects had been referred. Hypertension was selected as a test to determine if the high proportion of previously known cases reported might be due to a tendency of physicians to return the report form on previously known cases and to withhold it in cases where a new diagnosis had to be established. Although the percentage of forms returned increased with the number of suspects referred to the physician, there was no relationship between the percentage of returns and the percentage of "condition present" (table 2). Neither was any relationship found in the percentages having hypertension either newly diagnosed or previously known. Thus, it would seem that in estimating the number of conditions diagnosed from the partial returns by physicians no obvious bias is introduced.

Atlanta Program

The Atlanta multiple screening program was designed to blood test and X-ray large numbers of persons to find syphilis, tuberculosis, and

Table 2. Comparison of number and percent of "conditions" identified by physicians with number and percent of forms returned, Richmond Multiple Screening Survey

Percentage of forms returned	Physicians reporting	Suspects reported	Forms returned	Condition identified as present	
				Number	Percent
0-69-----	30	324	99	47	47.5
70-89-----	5	333	270	122	45.2
90-100-----	17	401	388	189	48.7

NOTE: More than one "suspect" referred to each physician in group whose surnames began with letter B.

other suspected conditions, through examination of the blood and the chest. Because of the large-scale nature of this endeavor, it was decided to concentrate on case finding and not to attempt to obtain data extraneous to that objective. Data on each individual responding to the appeal to come to the clinic were limited to age, race, and sex; no information was requested regarding schooling, income, or other socioeconomic factors.

Large numbers of persons were tested in Atlanta and large numbers with previously unknown conditions were discovered. But how successful was the project in terms of its potential? In making both case-finding and prevalence estimates, can it be assumed that the proportion of the population tested is the same as the proportion of the existing conditions found? In other words, as far as the condition being sought is concerned, do people come to the clinic at random? The 1950 census figures will indicate whether the young or the old, males or females, whites or nonwhites came in.

Unlike Richmond, Negroes are heavily represented among the respondents, with better representation than white persons for both sexes and at all ages. Moreover, the groups 15 to 34 years of age responded most. This is true of both races and both sexes. But how about the rich or the poor, the well educated or the not so well educated? Schooling was not checked on the Atlanta forms. The Bureau of the Census is currently preparing a tabulation for us which compares the education and income of the head of the house of the respondents and of the nonrespondents to the survey.

But how about biases inherent in the conditions themselves? Do the people who have syphilis or tuberculosis or diabetes come in to the clinic or stay out? More particularly, do the people who have been previously diagnosed as having a disease stay out or come in? The only way to find out is to examine either all or a sample of the nonrespondents.

Ideally, a sample should be selected before a screening project begins. After the project is completed, an attempt should be made to find and to examine those who did not respond to the public appeal. Since this had not been done, it was hoped that it would be possible to select a sample of the Atlanta population immediately after the project, check the responses against the survey records, and then attempt to examine the nonrespondents. However, funds were not available for a project of this type, so arrangements were made for analysis of a small sample of Negroes. This sample was selected by us and interviewed by staff members of Atlanta University, both for social-anthropological characteristics and for their participation in the Atlanta multiple screening program. The records were matched against the multiple screening records, and the sample of persons, all of whom were 15 years of age and over, was divided into two groups: those who responded to the appeal to come to the clinic for multiple screening; and those who did not. Letters were sent to all those not identified as respondents, inviting them to come to the city clinic for a chest X-ray and blood tests for syphilis, diabetes, and anemia. Few of the letters were returned as nondeliverable, and many of those in the sample selected came in for an examination.

One difficulty encountered was that this project was considered as research, for which insufficient funds were available. However, through the courtesy of the Georgia Division of Venereal Disease Control, two investigators were lent to us for 2 weeks, and an additional group of persons in the sample was induced to take the examination. At the end of 2 weeks the investigators returned to their usual tasks, leaving 560 of the 1,208 in the sample unexamined.

Because of the high percentage of positive blood tests (approximately 30 percent), it was

decided that further follow-up would be profitable. After the investigators had done their best to get the nonrespondents to come in for examination, teams went into homes and offices in an attempt to obtain blood from the most uncooperative cases. Because of technical difficulties, this test was limited to the blood test for syphilis.

Altogether, there were 2,449 Negroes 15 years of age or over in the sample examined. Of this number, slightly more than half responded to the survey appeal; of these, 84 percent were eventually tested for syphilis. The remaining 16 percent were listed as "uncooperative," "moved," "died," and "could not locate."

The results of the different phases of follow-up are given in table 3. The percentage of positive blood tests at all ages is much higher in the nonrespondents than in the original respondents to the survey. Moreover, the percentage is higher in the second phase of the follow-up of the nonrespondents in the sample than in the first phase, indicating an unwillingness to respond on the part of those with a high positivity rate. We cannot explain the lower rate in the most resistant cases—those which had necessitated a blood test at home. However, this rate is still much higher than the rate for the original respondents. Presumably then, in Atlanta, there were more cases of syphilis among those Negroes who stayed away from the survey than among those who came in.

X-rays for tuberculosis also showed a slightly higher percentage of positives among the nonrespondents (2.2 vs. 1.7) than among the respondents. However, for anemia and diabetes the opposite was true: the respondents showed higher abnormal rates than the nonrespondents (anemia, 9.6 vs. 8.2; and diabetes, 5.4 vs. 3.1).

Mississippi Project

A special syphilis case-finding project in Mississippi also provides data on nonrespondents. This project included an appeal to the public to have blood tests. At the end of a designated period a team went into homes and attempted to get samples of blood from those who did not respond to the appeal. In 9 out of 11 counties the percentage of positive blood tests among those tested at home was higher than among

Table 3. Results of serologic tests for syphilis for Negroes tested during the Atlanta multiple screening survey and as a result of follow-up

Age (years)	Respondents		Nonrespondents					
	Number	Percent	First phase		Second phase		Tested at home	
			Number	Percent	Number	Percent	Number	Percent
15-24-----	279	9.7	75	10.7	27	11.1	13	15.4
25-34-----	311	21.2	132	31.8	38	36.8	29	41.4
35-44-----	290	26.6	109	42.2	42	45.2	18	16.7
45-54-----	199	28.1	93	34.4	34	44.1	12	50.0
55-64-----	102	25.5	80	30.0	14	50.0	13	23.1

Total ¹ -----	1,241	20.8	541	30.7	174	36.8	91	29.7

¹ Includes one case, age unknown.

those who volunteered. In the 11 counties, the syphilis rate for nonrespondents was 11.8 percent compared to 8.0 for the respondents.

Georgia Case-Finding Project

A special case-finding project was carried out in a town in Georgia where, after the initial survey, an attempt was made to test the whole population. A slightly higher percentage of positives and a considerably higher rate of previously unknown syphilis was found in the nonrespondents than in the respondents (2).

Effect on Therapy Evaluation

Therapy evaluation is another area in which nonresponse affects finding of relapsed cases and estimates of prevalence of diseases needing re-treatment. Here we start with a group of persons who are known to have, and who know they have, a condition requiring medical treatment. They are treated and, whenever possible, all or part of the group are examined periodically, in an attempt to identify the persons who relapse or progress, and to determine failure or re-treatment rates. As in the usual type of case-finding project, the purpose of the follow-up is twofold: to find the failures and offer them further treatment; and to calculate failure or success rates. To induce treated persons to return for post-treatment observation, reliance can be placed on patient education and the patient's interest in his own health; on let-

ters urging him to protect his health by coming in for an examination; on follow-up by a worker who visits him and urges him to return to the clinic; and on visits to his home or place of business, where he can be at least partially examined.

Division of Venereal Disease Study

A special intensive follow-up study made by the Division of Venereal Disease affords opportunity to observe differences in re-treatment rates among patients followed up by special "research investigators" and patients followed routinely—by patient education or by letter (3). Both groups of patients were treated by the same clinics, during the same period, and by the same methods of treatment, the only difference being in the method of follow-up. Of the group followed routinely, 42 percent were observed for 2 years; of the intensively followed group, 92 percent. No sizable differences between the failure rates were noted after the first year (table 4). Throughout the first year, the cumulative failure rate is higher in the group that was observed more completely, possibly due to earlier detection of relapses. In the early months of observation, the seronegativity rate in the intensively followed group was higher, again undoubtedly due to more complete examinations. However, at the end of 2 years there was no appreciable difference between the re-treatment rates of both groups.

Table 4. Cumulative re-treatment rates of secondary syphilis patients in a group followed intensively and in a group followed routinely

Observation period (months after treatment)	Intensive follow-up (250 patients)	Routine follow-up (1,856 patients)
3	1.6	0.7
6	6.4	4.8
9	10.9	7.9
12	11.7	11.1
15	12.9	13.2
18	13.7	13.9
21	15.0	14.8
24	15.0	15.8

Summary

1. Failure to respond to an appeal to "know for sure," when addressed to persons who are apparently well or who are being treated for various conditions, presents problems for both the case finder and the statistician.

2. Evidence from Richmond, Va., and Atlanta, Ga., suggests that the general public does not respond to such appeals at random, but that certain segments of the population respond better than others, because of the type of appeal or because of other factors.

3. These differences in response affect the observed prevalence of some diseases in the groups responding, when the presence of these conditions is affected by age, race, sex, or socioeconomic or other factors.

4. Knowledge of the presence or absence of the conditions being studied may affect the person's decision to respond to the appeal to have an examination.

5. Data from both Atlanta and Mississippi show higher syphilis prevalence in nonrespondents. In Atlanta, somewhat higher tuberculosis rates, but lower anemia and diabetes rates, are found among nonrespondents than among respondents.

6. Data from the Richmond multiple screening survey show no differences in the proportion of morbidity reported by physicians for suspects referred to them, regardless of the percentage of suspects reported on.

7. Data from the Division of Venereal Disease of the Public Health Service show no differences at the end of 2 years in cumulative re-treatment rates between a group of patients followed routinely (42 percent) and a group followed intensively (92 percent).

Effective Use of Dental Assistants

By GEORGE E. WATERMAN, D.D.S.

Provision for adequate personnel to meet current demands for dental care services poses a challenge to the dental profession. Proved preventive measures can reduce the need, but, even if it were possible to apply preventive measures on a nation-wide scale, the need for dental care services would greatly exceed the capacity of the dental profession to supply them. And the prospect of a real increase in the number of dentists within the immediate future is not good.

According to Schoeny (1), "As nearly as it is possible to estimate, 9,200 dentists over and above those now in sight for the year 1954 will be required to maintain the present level of civilian dental services, to meet the special needs of industrial mobilization, to meet the minimum needs of an adequate civil defense program, and to meet the projected needs of the Armed Forces based upon a ratio of 2 per 1,000 troops strength. It is at once apparent that a substantial deficiency in dental manpower is already upon us and this deficiency is steadily increasing. It will not be possible to avoid or even reduce this deficiency before 1954. Whatever the demand, the present supply of dentists must meet all needs until then, or as soon thereafter as the training of additional dentists not now in process of education can be completed."

It seems imperative, therefore, that serious

Dr. Waterman directed the Richmond (Indiana) Dental Study. He is now with the Division of Dental Public Health, Bureau of State Services, Public Health Service. The paper was presented before the American Dental Association, October 17, 1951.

consideration be given to other means of increasing our capacity for providing dental care services.

One of the most rational and noncontroversial means of meeting this problem is through the effective utilization of trained assistants. The medical profession is far ahead of the dental profession in the use of auxiliary personnel. Physicians long since have realized the necessity and importance of increasing their professional services through effective use of auxiliary personnel.

Klein (2) estimates that the patient load per dentist can be increased from 33 to 75 percent through the use of trained assistants (fig. 1). Moen (3) found a great variation in the number of patients treated per dentist, according to whether or not the dentist employed auxiliary help. He found that dentists who employed one assistant averaged 37 percent more patients than those without such employees, while dentists employing two assistants averaged 69 percent more patients. These estimates are probably conservative.

Klein (2) also has estimated that approximately 55 percent of the dentists of this country employ dental assistants. Reporting for the bureau of economic research and statistics of the American Dental Association, Moen (4) found that 65.5 percent of the dentists responding to a survey employed at least one full-time dental assistant, technician, or hygienist. He estimated the total number of full-time dental assistants to be 55,200, assuming that there are 76,000 practicing dentists.

Unfortunately, only a relatively small number of dentists employing assistants utilize them to their full potential effectiveness. A review of the literature reveals a striking lack of specific information regarding the techniques

of good chairside assistance. Much time and space has been devoted to instruction in such duties as keeping the office neat and attractive, proper maintenance of equipment, sterilization of instruments, processing X-rays, making appointments, bookkeeping, and answering the telephone. All of these duties are essential to the efficient operation of a dental office or clinic. But it is unrealistic to expect that one dental assistant can perform these duties and still give effective chairside aid to the dentist. Adequate personnel should be employed to take care of both types of duties.

Use Requirements

The dentist should have a broad working concept of how to utilize assistants effectively. Through application of this concept and through experience, he must develop efficient utilization of personnel. The assistant must be fully informed of duty details and develop competence in their performance. Adequate auxiliary personnel must be available so that both the chairside assistance and the other duties of the office can be carried out efficiently and without interruption. Teamwork must be highly developed and coordinated.

Results to be expected are:

- 1. More dental-care services can be provided through use of a trained assistant because she

conserves the dentist's time by performing the numerous tasks incident to routine dental treatment, which the dentist would otherwise have to perform himself.

- 2. Quality of services is also improved because the dentist is under less physical and mental strain. He is able to concentrate his attention on what he is doing; he enjoys his work more, and, therefore, should produce better-quality work.

- 3. Better control of the patient is possible through the influence of an assistant.

- 4. Less mental and physical strain result since the activities incident to the service are being shared. The necessary armamentarium is as near as the dentist's hand. He can work from the seated position during the entire treatment procedure, and be less fatigued.

- 5. Provision of more services results in greater patient turn-over, which brings greater income.

- 6. The resultant increase in the number of patients treated decreases the tooth mortality rate per patient, reduces the incidence of caries through early detection and treatment, and makes available to the dentist more time for providing preventive treatment.

- 7. The technique of preparing cavities under water is readily accomplished with the help of a chairside assistant. Also, the appointment periods are shorter, resulting in less pain and discomfort to the patient.

These conclusions are based on the results of the Richmond study, where the emphasis has been placed on the effective utilization of dental assistants.

The Richmond Study

The complex problem of accumulated dental needs among children provided the basis for a 5-year clinical study of dental care, which was carried on in Richmond, Ind., by the Indiana State Board of Health and the city of Richmond, with the cooperation of the Public Health Service. The study began in December 1946 and was concluded in December 1951. One objective was to explore, under practical operating conditions, the possibilities of extending the services of dentists through the effective utilization of qualified auxiliary per-

Figure 1. Percent increase in patients treated by dentists with chairside assistants. Percentage base is work of single dentist without an assistant—from Klein (2).

sonnel, and thus to provide a basis for intelligent appraisal of dental manpower requirements in this and comparable communities.

There was a personnel assignment of approximately one and one-half trained assistants per operator, plus necessary clerical personnel and two complete units per operator.

The following personnel were on duty: five dentists, seven dental assistants, two clinic clerks, one oral hygienist, one dental health educator, and one stenographer.

Complete treatment, with the exception of orthodontics, was provided annually to approximately 5,500 children, from kindergarten through junior high school. Service of high quality was required and provided. We found that increased services develop naturally as the operator masters the techniques of efficient utilization of trained auxiliary personnel.

Several months prior to the inception of this research program, representatives of the Division of Dental Public Health of the Public Health Service spent considerable time in the offices of Dr. Roy O. Elam, Nashville, Tenn. His counsel and his demonstration of the effective use of dental assistants indicated that such a method would be practical in school dental clinics. Dr. Elam was a consultant from the beginning of the study.

The five dental assistants initially assigned to the Richmond study received 10 weeks of intensive training at the Naval Dental School, Bethesda, Md. There was some turnover in personnel. A new trainee began as clinic clerk. In addition to clerical duties, she devoted time to training as a dental assistant. Most of the training was provided by the experienced assistants.

Training included close observation of clinic routine; instructions in maintaining cleanliness and in the techniques of sterilization; learning the names, numbers, and location of the various instruments, and the proper set-up of instruments on the bracket tables; and, finally, specific use of each instrument and the routine of its use by operators in a clinic. During this training, in addition to becoming proficient as a clinic clerk, the trainee became an "aide" to the second, or roving, assistant. Three to four weeks of such training usually proved sufficient to qualify a trainee as a full-time second, or ro-

ing, assistant. Three weeks as second assistant usually qualified her to become a chairside assistant. A trainee normally developed into an efficient chairside assistant in from 6 to 8 weeks of training.

Effect on Procedures

The use of chairside assistants modifies the usual procedure at the chair. The dentist, for example, can work from a seated position. The following description is illustrative.

Before the dentist takes his position on the operating stool, the chairside assistant has prepared the patient for treatment by properly adjusting the chair, and has provided the appropriate instrument set-up on the bracket table. If anesthesia is to be used, she prepares the syringe, hands it to the operator in such a manner as not to alarm the patient, and takes necessary precautions to guard against any sudden movement by the patient during the injection. As soon as the assistant knows which tooth is to be worked on, she places the proper bur or diamond instrument in the contra-angle and hands it to the dentist.

During the cavity preparation, the assistant flows water over the revolving bur or diamond instrument, retracts the tongue or cheek as required, using the saliva ejector to retract the tongue and her finger to retract the cheek. She dries the cavity for intermittent inspection and hands cutting instruments to the operator as required.

When the cavity is prepared, the chairside assistant isolates the tooth with cotton rolls and dries the cavity with cotton pellets and air. If a base is to be used, the dentist calls for it as the cavity preparation is being completed, so that by the time the cavity is ready for a base, a second assistant has mixed the cement and placed it on the bracket table; at this time she removes the contra-angle from the handpiece, replacing it with the automatic condenser containing the proper condensing point. The chairside assistant meanwhile has provided the matrix retainer and the band as requested. In a few seconds the operator can place the base and adjust the band. While he is doing this, the second assistant is mixing the alloy, which she places on a piece of gauze on the bracket

table. She removes all instruments from the table, with the exception of the condensers, carvers, mirror, explorer, and cotton pliers.

The filling material, in this instance alloy, is placed in the prepared cavity by the chairside assistant. As she places each carrierful, she hands the operator the condensers in the sequence in which he uses them.

During the carving of the filling, the chairside assistant hands the carvers to the operator in proper sequence, at the same time using the air syringe to blow away the amalgam scrapings.

Operators must develop techniques in which they use a minimum number of instruments and make proper use of such instruments to avoid confusing the chairside assistant. In this way the average assistant is soon able to anticipate the operator's every need.

While the chairside assistant is providing the afore-mentioned services, the second assistant is busy elsewhere in the clinic with such duties as preparing the next patient for treatment, cleaning and sterilizing instruments, mixing amalgam or cement, developing X-rays, or performing any one of the other innumerable duties. She also is capable of substituting for the chairside assistant at any time that it becomes necessary.

Every effort is made to conserve the time of the dentist. Each operation is analyzed to determine just which parts of the work should be delegated to assistant personnel.

Time and Motion Saved

In preparing the script of a motion picture (see illustrations) of the clinical aspects of the Richmond study, it was necessary to list the activities of the dentist, the chairside or first assistant, and the roving or second assistant. Including the seating of the patient, anesthesia, cavity preparation, the filling of three teeth with amalgam, carving of fillings, and dismissal of the patient, the number of activities were as follows: dentist, 33; first assistant, 57; second assistant, 39. The technique followed was routine; the number of instruments used and movements required were kept to a minimum consistent with high-quality service.

For this type of three-filling procedure, the difference in the workload when done by a dentist alone, with one, and with two assistants is shown in figure 2.

True, many of the activities performed by the dentist and the first assistant were synonymous, such as handling and receiving the various instruments. Such activities totaled 22,

Film Demonstrates Use of Dental Assistants

Title: Dental Assistants—Their Effective Utilization, 16-mm., sound, color, 20 minutes, 1951 . . . Audience: dentists, dental assistants, dental students . . . Available by loan through State health departments; by purchase from Byron, Inc., 1226 Wisconsin Avenue, NW., Washington, D. C.

These pictures from the Public Health Service motion picture show how dental assistants were used in the 5-year dental health demonstration project in Richmond, Ind., sponsored by the city, the State health department, and the Public Health Service's Division of Dental Public Health.

The advantages to both dentist and patient of using two chairs and two dental assistants are shown for several dental procedures.

The film does not attempt to present the technique of training dental assistants to the high degree of coordination and timing demonstrated in the film, but it does emphasize that this training is not difficult and that much can be accomplished in as little as 6 weeks.

The film underscores the concept that multiple chairs and assistants are one answer to the big question: "How can a limited number of dentists take care of an increasing number of people seeking dental attention?"

Reporting record cards and simple administrative reports prepared by the local register clerk help to keep local and State health department personnel informed of register activities.

Detailed tabulations and analyses are prepared in the State Department of Health, where special tabulating facilities and personnel trained in statistical techniques are available.

The State records consist of a single alphabetic file of case folders, divided into active and inactive cases. Each folder contains all the reports received on a case. In addition, for each calendar year there is a file of punched cards, one card for each case active during the year. These cards may be used for annual tabulations, or cards for more than 1 year may be combined for analyses requiring a large number of cases.

As a result of such procedures as the use of the same code sheet for a 10-year period and the coding of information (other than new cases) only once a year, practically all coding and punching is completed in a relatively short period of time. More clerical time is therefore available for such tasks as assisting in the preparation of analyses of the data. After all, without adequate summaries of the cancer experience reported, the data in the files serve no useful purpose.

Staffing Requirements

For the successful operation of a cancer register of the kind and scope described, the services of the following types of personnel are required: in the local health department, the county health officer, public health nursing supervisor and staff nurses, and a secretary or clerk; in the State health department, a medical officer, public health nursing supervisor or consultant, statistician, clerical personnel, punch card operators, and machine tabulating personnel.

It is not necessary that these services be full-time. Each type of person enumerated, however, has special skills to contribute to the efficacy of the program. The assistance of the county health officer, county and State public

health nursing supervisors, and State cancer control director, for example, although largely advisory, is essential for the guidance and maximum utilization of the register, and the acceptance of the program in the community.

The question naturally arises as to how much time is required to operate a program of this type. It did not seem practical to determine the amount of professional time involved, but it was possible to conduct a 2-month study to determine the number of clerical man-hours required to operate the cancer register program in the local and State offices. The table below indicates that little more than two clerk-days a month (or approximately one-half clerk-day a week) are required to maintain a cancer register in a local health department serving a population of approximately 80,000.

Number of man-hours required per month to operate local cancer register (exclusive of nursing service)

County ¹	County population (1950)	Active registered cases (June 30, 1951)	Man-hours per month to operate register
Harford.....	52,000	83	6½
Frederick.....	62,200	228	16¼
Washington.....	78,700	368	16½
Total.....	192,900	679	39¼

¹Montgomery County, with a population (in 1950) of 163,700 and 427 active registered cases on June 30, 1951, is not included, since the register work performed in this county during the 2 months of the time study was atypical of routine procedures.

Although, in comparison with other local health department operations, relatively little time is spent on cancer register activities, it is interesting to see how this time is accounted for by type of cancer register activity. The total 39¼ clerical hours per month for cancer register work in the three counties is distributed as follows:

1. Receipt and posting of current reports and information to register card, and register services to public health nurses, such as transcribing information from cancer register card to nursing service record for cases newly opened to service—19½ hours, or 50 percent of the total time.

2. Sending requests for case reports to medical agencies known to have seen an unreported case— $8\frac{3}{4}$ hours or 22 percent.

3. Sending requests for follow-up reports to medical agencies— $7\frac{3}{4}$ hours or 20 percent.

4. Preparing administrative reports— $3\frac{1}{4}$ hours or 8 percent. (This figure is somewhat higher than a true monthly average since a semi-annual report was prepared during one of the two months in which clerical time was recorded).

As reporting improves, the $8\frac{3}{4}$ hours (one-fifth of total register time) required to request case reports will be reduced. Differences between the counties in man-hours used in conducting register activities may be attributed in part to different reporting problems in each county.

In the State office, approximately $1\frac{1}{3}$ persons are required full time to perform the routine register operations of filing reports, abstracting cause-of-death information, coding basic information for newly reported cases, correspondence, and occasional visits to the counties to discuss reporting and register problems. In addition, it takes 2 persons approximately 6 weeks annually to code current information on cases in the active register (2,000 cases in 1951), exclusive of the time used for preparation of punched cards and tabulations.

The above data illustrate that, from the standpoint of workload, the cancer register procedures developed in connection with this program represent a feasible and practical system of operation.

Statistical Findings

What statistical findings with respect to cancer patients in the four counties have been revealed by this study? Findings of the first 2 years of operation are described in "Cancer Illness Among Residents of Four Maryland Counties, 1948 and 1949," which is to be published by the National Cancer Institute of the Public Health Service. A summary of this report follows.

The estimated total population of the four study counties (Frederick, Harford, Montgomery, and Washington) during 1948-49 was about 340,000, including urban, semirural, and

Figure 1. Comparison of cancer incidence, prevalence, and mortality in four Maryland counties, 1948 and 1949.

rural communities of varying sizes. In 1940, one-half of the population was rural nonfarm and one-fourth, rural farm. This is one of the few instances where data are available on cancer illness for an area with a large rural population. Therefore, it is interesting to compare the Maryland data with National Cancer Institute data based upon morbidity surveys of five urban areas (Atlanta, New Orleans, Pittsburgh, Denver, and San Francisco).

Number and Kinds of Cases

During 1948 and 1949, an average of 650 newly diagnosed cases of cancer was reported yearly among residents of the four counties in the study. Each year a total of 950 persons were reported ill with cancer, and 450 deaths were attributed to this disease. It is believed, however, that a substantial number of diagnosed cancer cases were not reported. Based on the number of registered county deaths and on the ratio of diagnosed cases to registered deaths in the group of five surveyed cities, it is estimated that there was actually a minimum of 1,300 persons ill with diagnosed cancer each year, 900 of these newly diagnosed. In the five surveyed cities, an average of three diag-

nosed cancer cases was found for each registered cancer death, two of which were newly diagnosed. In addition to the cases of diagnosed cancer, there was an undetermined number of undiagnosed cases which will remain undetected until later years.

More newly diagnosed cases of cancer were reported among females than among males during 1948 and 1949 in each county except Harford. A total of 737 cases in females was reported, compared with 600 cases in males (a ratio of 1.2 cases in females to each case in males). Five percent of the reported cases were in nonwhite persons.

The digestive system was the principal site of cancer among both male and female patients who were newly diagnosed (fig. 1). However, cancers of this site were relatively more frequent among males (31 percent of all cases in males compared with 26 percent in females). The skin and genital organs were the next most frequent sites among males; genital organs and the breast, among females. Together, the last two sites accounted for almost half of all cases in females.

*Excludes leukemias and lymphomas.

Figure 2. Comparison of newly diagnosed cancer cases, diagnosed while localized, in four Maryland counties and in United States five-city sample. (Data based on cases for which stage at diagnosis was reported.)

Although some forms of cancer (lymphomas, leukemias, brain and bone tumors) occur frequently among younger persons, cancer is largely a disease of late adult life—70 percent of the newly diagnosed cases were among patients 55 years of age and over. In general, cases in the female were diagnosed at a slightly younger age than cases in males (an average of 60 years compared with 63). This may be explained in part by the predominance of malignancies primary in the genital organs and breast among females. Cancers at these sites occur at younger ages than do cancers that predominate among men (cancers primary in the digestive and respiratory systems, skin, and male genital organs). Incidence and prevalence rates per 100,000 population would greatly assist in the analysis of these data; unfortunately, these rates cannot be determined until a greater proportion of diagnosed cancer cases are reported.

The average cancer mortality rate per year was 133 deaths per 100,000 population in the four counties studied, compared with a mortality rate of 143 for the total United States. The mortality rate was highest in Frederick County (164 per 100,000) and lowest in Montgomery County (115). In part, these differences may be explained by the age composition of the county population. To evaluate the influence of age upon mortality, age-standardized mortality rates will be computed when 1950 population data become available.

Diagnosis, Treatment, Other Medical Care

It appears from the data collected that more intensive case-finding programs are needed to aid in the early discovery of cancer cases. Only half of the newly diagnosed cases were discovered while localized at site of origin (fig. 2). Three out of every ten cases were found after the neoplasm had metastasized to regional tissues, and 2 out of every 10, after remote tissues had become involved. Cancers of inaccessible organs generally went undiagnosed until a late stage. A smaller but still substantial proportion of cancers of accessible sites were also undiagnosed until a late stage. For example, 63 percent of all breast cancers and 51 percent of cancers of female genital organs were diagnosed after metastases had occurred.

Another criterion for adequacy of medical care is the proportion of diagnoses confirmed by microscopic examination. Of the cases newly diagnosed in 1949, 68 percent were confirmed microscopically, about the same percentage as that found in the United States sample of five cities.

Surgery alone was the primary course of treatment for over half of the cases for which information was available. Seventeen percent of the patients received radiation therapy only, while 8 percent were treated by both surgery and radiation. About 2 out of every 10 patients were not treated or received only palliative therapy. In this category were a relatively high proportion of cases of leukemia (75 percent) and cancers of the respiratory and digestive systems (45 and 34 percent, respectively). Nontreated cases were reported among these cancers even if discovered while localized. Some of these cases, however, may have received treatment which was not reported.

The average duration of first hospitalization for newly diagnosed cancer cases was 17 days. The total number of days of first hospitalization for cancer for patients residing in the four counties is estimated to be between five and six thousand yearly, including in-patient days in out-of-county hospitals. If all hospitalizations for cancer cases during a year are considered, regardless of the frequency of hospitalization or the date of diagnosis, one may estimate a total of 9,000 hospital days a year for resident cancer cases.

Another important index of the quality of medical management of cancer cases in a community is the continuity of medical care. Continuous medical supervision of cancer cases is needed to assure that a reappearance of cancer symptoms will be detected promptly. However, 83 persons ill from cancer in 1948 were not reported seen by any medical agency in 1949. Some of these patients were ill when last seen by a physician and had not returned for further treatment. Although one-fourth were cases of skin cancer, cases no longer under medical supervision were reported for cancers of the breast, digestive system, and other sites with relatively poor prognosis.

Since the performance of an autopsy is considered desirable for the confirmation of the

Figure 3. Survival experience of cases of cancer newly diagnosed during 1948 and 1949 in four Maryland counties, by stage at diagnosis and by selected site of cancer. (Survival for 24 months not shown in some instances, because of insufficient data.)

cause of death and for furtherance of knowledge of the disease, information was collected on whether or not an autopsy was performed for each death attributed to cancer. It was found that autopsies were performed in only 9 percent of cases in which cancer was reported as the cause of death. This percentage was even lower than the percentage of autopsies among deaths from all causes (12 percent).

Survival and Apparent Recovery

Rates of survival and apparent recovery from cancer are useful tools in measuring the success of cancer case management. Information on the probability of survival and recovery can also assist the physician in determining the optimum frequency of follow-up examination and the intervals within which the disease is most likely to recur.

Figure 4. Comparison of total survival rates and symptom-free survival rates for cases of cancer newly diagnosed during 1948 and 1949 in four Maryland counties.

Calculated on the basis of a modified life table method, 53 percent of cases newly diagnosed with cancer in 1948 and 1949 survived 1 year after diagnosis; 37 percent survived 2 years. The rate of attrition was higher during the first several months after diagnosis than during subsequent months.

The chances of survival were considerably higher for females with cancer than for males—44 percent of females with cancer survived 2 years as compared to 28 percent of males. This difference is due principally to the larger proportion of cancers among males primary in sites with poor prognosis, such as the digestive and respiratory systems.

Survival rates by stage at diagnosis illustrate very strikingly the importance of early detection: 67 percent of cases diagnosed with a localized cancer survived 18 months compared to 35 percent for cases diagnosed with regional involvement and 9 percent for cases diagnosed

with remote or diffuse metastases (fig. 3). The lowest 18-month survival rates (5 percent) were among cases with cancer of the stomach (fig. 3). The survival rate of cancer of the respiratory system was also low (15 percent).

The 1-year survival rate of 53 percent for cases resident in the four counties is lower than the survival rate of 67 percent obtained for cases in the United States sample of five cities. To what extent this difference is a reflection of incomplete and selective reporting in the Maryland counties and to what extent the data represent true differences in survival experience of cancer cases cannot be determined at the present time.

The proportion of county cases diagnosed with cancer who were both alive and clinically free from cancer at the end of 1 year is estimated at approximately 35 percent (fig. 4). Thus, one might say that while half of all county residents who develop cancer will be alive one year after diagnosis, only one-third will be both alive and clinically free from the disease. All but 2 percent of those who die during the first year will die with cancer present at time of death.

Not only is there marked variation in survival rates by stage at diagnosis, there is also considerable variation in the proportion who are symptom-free among the survivors. The proportion of newly diagnosed cases alive and symptom-free at the end of 1 year represented 59 percent of the cases discovered while localized, and 23 percent of those diagnosed after regional metastasis.

Differences in survival and apparent recovery by cancer site and by county are shown in the detailed report. However, the relatively small number and selection of reported cases makes it unwise to consider these data as conclusive of true differences in survival experience. It appears essential to continue the collection of data on this and other aspects of cancer illness in the four counties.

New Media for the Differentiation of Enteric Bacteria

By HECTOR COLICHON, M.D.

Although a number of methods have been devised for rapid identification of colonies of enteric bacteria which appear on plates of differential media inoculated with fecal material, further improvement of these methods is needed. The two media described here have been used successfully by the author, and it is believed that their adoption will result in more rapid recognition of the pathogenic genera and in economy of time, materials, and labor. The compositions and methods of preparation of the media are as follows:

"IM" Medium

A. Basic medium:

Proteose peptone (Difco)-	10.0 gm.
Sodium chloride-----	5.0 gm.
IM indicator-----	10.0 ml.
Distilled water to make---	1,000.0 ml.

IM indicator is prepared by adding 0.4 gm. of thymol blue to 100 ml. of Andrade's indicator. The peptone and salt are dissolved in the distilled water, the reaction adjusted to pH 7.4, and the indicator added. The medium is distributed in 3-ml. amounts into 100 x 13 mm. test tubes which contain Durham inserts, and

the tubes sterilized for 15 minutes at 15 pounds' pressure. Care should be taken that all air is expelled from the Durham tubes.

B. Triple carbohydrate solution:

Lactose-----	30.0 gm.
Mannitol-----	1.4 gm.
Sucrose-----	1.4 gm.
Distilled water to make---	165.0 ml.

Substances of the highest purity obtainable should be used. After the materials are dissolved, the solution is sterilized by filtration, and stored in well-stoppered tubes in the refrigerator.

C. Urea solution:

A 20-percent urea solution is sterilized by filtration, distributed in stoppered tubes and stored in the refrigerator.

Add 5.0 ml. of urea solution to 8.2 ml. of carbohydrate solution and pipette 0.4 ml. of the mixture into each tube which contains 3.0 ml. of the basic medium. Incubate for 24 hours to insure sterility.

"SMG" Medium

A. Basic medium:

Proteose peptone (Difco)-	5.0 gm.
Tryptone (Difco)-----	15.0 gm.
Lead acetate (neutral, C. P.)-----	0.5 gm.
Sodium thiosulfate (crystals, C. P.)-----	0.2 gm.
Agar (Bacto, Difco)-----	14.0 gm.
Phenol red (0.2 percent solution) -----	15.0 ml.
Distilled water to make---	1,000.0 ml.

Dr. Colichon is from the Instituto Bacteriologico, Lima, Peru. This is a revision of an article originally published in Revista Peruana de Pediatria. The new data here included were obtained while the author was working as a student in the enteric bacteriology unit of the Public Health Service Communicable Disease Center in Atlanta.

Dissolve the peptone, tryptone, and agar in a boiling water bath. Dissolve the lead acetate and the sodium thiosulfate in a small amount of distilled water and add to the peptone-tryptone-agar solution. Adjust the medium to pH 7.4 to 7.5 and add the indicator. Distribute in 100- or 200-ml. amounts in suitable flasks and sterilize for 15 minutes at 15 pounds' pressure.

B. Double carbohydrate solution:

Mannitol..... 20.0 gm.
Glucose..... 2.0 gm.
Distilled water to make..... 110.0 ml.

Dissolve the carbohydrates and sterilize by

filtration. Distribute aseptically in well-stoppered tubes in amounts of 5.5 or 11.0 ml.

To 100 ml. of melted and cooled basic medium add 5.5 ml. of the double carbohydrate solution, mix well, and distribute aseptically into 100 x 13 mm. tubes in amounts of 3.0 to 3.5 ml. Allow to solidify in a slanting position so that a deep butt is present. Incubate 24 hours to insure sterility.

In IM broth, urea utilization is indicated by production of alkali and consequent development of a blue color due to the presence of thymol blue. Acid production results in the development of a red color by the Andrade's indicator. The reading of the results in SMG

Mannitol fermenters:							
<i>P. rettgerii</i>	+	—	—	—	++	—	
<i>Escherichia</i> :							
H ₂ S positive.....	—	+	++	++	+	++	
H ₂ S negative.....	—	+	++	—	+	++	
<i>Acrobacter</i>	—	—	++	—	+	++	

Key to the symbols:

— negative.
+ positive.
± late, very weak, or may even fail to appear.
—/+ neutral or alkaline slant, acid butt.
++ strong or very strongly positive.
—/++ negative to strongly positive.

agar is similar to the recording of reactions in Kligler's iron agar.

The media are inoculated with a thin platinum wire which is bent at an obtuse angle 1.5 to 2.0 mm. from its lower end. Each suspected colony is subcultured to IM broth, using a liberal inoculum which should be well distributed throughout the tube. The wire is sterilized and dipped into the inoculated broth, smeared on the surface of the SMG agar slant, and stabbed to the bottom of the tube. The tubes are incubated overnight at 37° C. The reactions of various groups of enteric bacteria in the two media are given in the accompanying table.

By incubating the tubes for several days, delayed fermentation of lactose or sucrose may become apparent. Often it may be desirable to test the action of the organisms on lactose, sucrose, adonitol, and salicin in the conventional manner. With many cultures, tests for indol, acetyl-methyl carbinol, citrate utilization, and motility will be necessary to confirm the tentative diagnosis.

The following notes may be helpful in the interpretation of the reactions:

1. Cultures which produce a strong acid reaction with abundant gas formation in IM broth and which do not blacken SMG agar are *Escherichia*.

2. When the amount of gas in IM medium is more than a small bubble, acid production is not apparent, and the turbidity is greater than usual; when a heavy growth is present in SMG medium, the inoculated organisms are not *Salmonella* or *Shigella* but are paracolon, *Escherichia*, or *Klebsiella*.

3. Cultures which produce a strong alkalinity in IM medium are *Proteus*. Reactions of different species are given in the table.

4. *Salmonella paratyphi A* and *Salmonella choleraesuis* do not blacken SMG agar.

5. Mannitol fermenting *Shigella* forms and anaerogenic *Salmonella* cultures produce similar reactions in the media and should be distinguished by motility and agglutination tests.

6. *Shigella* cultures which do not ferment mannitol produce no change in IM medium. *Shigella*-like paracolon strains and some *Proteus morgani* cultures give similar reactions but their greater growth vigor and characteristic odor aid in differentiation.

Growth from the surface of SMG agar may be suspended in saline and used as antigen in slide agglutination tests. Polyvalent *Shigella* serums, polyvalent *Salmonella* serums, and grouping serums for the two genera should be used to establish a rapid diagnosis of pathogenic forms which may be present.

Summary

Two media, IM broth and SMG agar, are described. By simultaneous inoculation of these media with colonies from plates inoculated with fecal material, it is possible to establish a rapid diagnosis of the enteric bacteria present. By their use it is possible to determine fermentation of glucose, mannitol, lactose, and sucrose; gas production, urea utilization; and H₂S production in two tubes. Results should be confirmed by appropriate biochemical and serological tests.

Clinical Traineeships

Graduates of approved medical schools may apply for clinical traineeships at the National Institute of Arthritis and Metabolic Diseases.

The new trainee program is designed to increase competency in the treatment and rehabilitation of arthritis patients. It will cover the prevention, diagnosis, and treatment of arthritis and metabolic diseases. Trainees without dependents will receive \$3,000 per year; with dependents, \$3,600.

For their course of study, trainees may select a qualified institution. Applicants must be American citizens not over 40 years of age, and must have completed a year's internship at an approved hospital.

Additional information and application forms may be obtained from: Chief, Extramural Programs, National Institute of Arthritis and Metabolic Diseases, Bethesda 14, Md.

Venereal Disease Morbidity, 1951

Syphilis Rates

In the 1951 fiscal year 198,640 cases of syphilis in all stages were reported for the first time to the Public Health Service. This represents a reported syphilis case rate of 132 per 100,000 civilian population. The geographic distribution of total syphilis cases reported per 100,000 population is shown in figure 1.

The number of syphilis cases reported has declined steadily since 1947. For the country as a whole, reported syphilis rates decreased by 49 percent, from 261 cases per 100,000 civilian population in 1947. In all States except Iowa, the reported syphilis rate has decreased as compared to 5 years ago (fig. 3). The relative size of the decreases in the various States does not appear to be correlated with the level of the syphilis rate in 1947. Since 1947 there has been a considerable decrease even in the States that had a low reported morbidity at that time.

Factors Influencing Rates

A number of factors may account for the changes in syphilis morbidity rates in the last 5 years, and the relative importance of these factors may vary widely from State to State. These factors include the relative efficiency of case finding in 1951 compared to 1947, including both the type and intensity of case-finding effort; the size of the backlog of undiscovered cases, i. e., case-finding efficiency prior to 1947; completeness of reporting both during the 5-year period and prior to it; population changes during the period; and decrease in incidence not associated with effects of the

The Division of Venereal Disease of the Bureau of State Services, Public Health Service, has prepared this section.

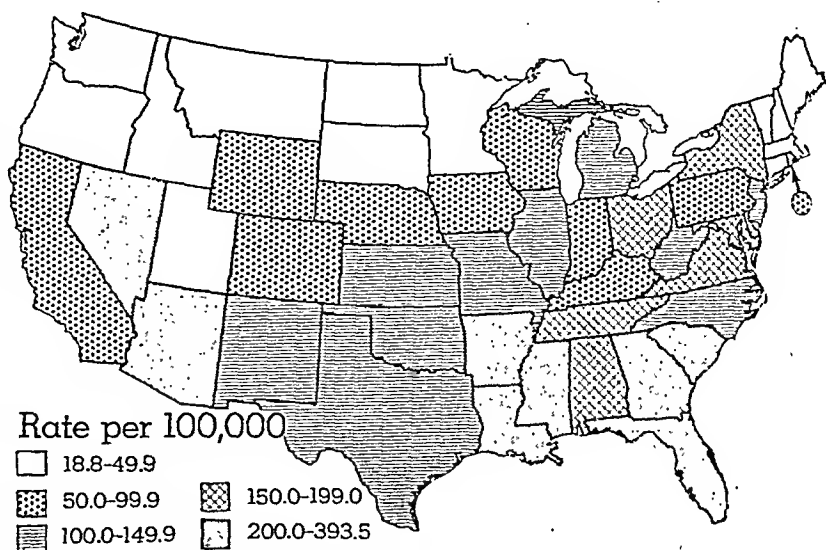

Figure 1. Reported syphilis case rates per 100,000 civilian population, fiscal year 1951.

control program, such as changing socioeconomic conditions and population mobility.

During the 5-year period there was no recorded evidence to indicate a letdown in case-finding activities. As far as public clinic activities are concerned, diagnostic observations

increased from 1,373,000 in the fiscal year 1947 to 2,359,000 in 1951. Neither is there any evidence to indicate that case-finding activities in fiscal 1951 were of poorer quality or less well directed at groups in the population who are most likely to be infected.

Figure 2. Trend in early syphilis and gonorrhea reported case rates, continental United States, civilians, fiscal years 1941-51 (includes primary, secondary, and early latent).

Figure 3. Percentage decrease in reported syphilis case rates for each State from fiscal year 1947 to 1951.

To understand the implications of syphilis morbidity statistics, it is important to realize that the stage of disease being reported may vary from primary to paresis, and the duration from less than 1 month to 30 years or more. All cases not previously reported, regardless of duration, should be included in current case reports. Therefore, the total of reported syphilis cases in any one year does not connote incidence data for that year even if case reporting were complete.

Because of the nature of syphilis, neither can prevalence data be directly inferred from morbidity data. Many cases in the population are excluded from current morbidity reporting because they have been previously reported for the same infection. While total syphilis morbidity or number of cases reported for the first time may not be properly applied directly to either incidence or prevalence, it has considerable value as an expression of the volume of successful case-finding activity.

Furthermore, the number of cases in the early stages of syphilis is useful as a minimum base for estimates of incidence, and the number of cases in the later stages may be considered as an indication of past case-finding failure. For the most part, gonorrhea cases reported may be used as a minimum base for estimating incidence. If these points are kept in mind, the data presented in the table and in the figures will be more meaningful. All data are for civilians only and by fiscal year.

Gonorrhea Declining Slowly

The trend in gonorrhea cases reported per 100,000 population has also been downward since 1947 (fig. 2). The numerical decrease has closely paralleled the decrease in early syphilis reported case rates (including primary, secondary, and early latent). Relatively, however, gonorrhea has decreased much more slowly. Reported gonorrhea rates in the fiscal year 1951 represent a decrease of 36 percent over 1947 while early syphilis rates decreased by 69 percent. In 1951, there were 179.2 cases of gonorrhea reported per 100,000 civilians.

Source of Morbidity Reports

Since syphilis is a reportable disease in all States, morbidity reports are received from private physicians as well as from clinics, hospitals, and other public facilities. Although we know that morbidity reporting is not complete, some indication of the relative volume of successful case-finding activity can be obtained by comparing reporting by public facilities and reporting by private physicians. In the fiscal year 1951, about two-thirds of all syphilis was reported by public facilities and one-third, by private physicians. Four-fifths of the reports of congenital syphilis were received from public facilities. Only 14 percent of the gonorrhea cases were reported by private physicians.

Race and Sex

Morbidity data reported to this division are classified by race and sex. In actual numbers of cases in the fiscal year 1951, about 1.8 times as much syphilis was reported among nonwhite persons as among white

(figs. 4 and 5). In terms of syphilis case rates specific for race and sex, however, the rates for white males and for white females are 60.2 and 44.9 per 100,000, respectively, while the rates for nonwhite persons are 765.8 per 100,000 for males and 810.7

for females. Among white persons, the rate for males is higher than for females, but among nonwhite persons the reverse is true. Gonorrhea cases reported among nonwhites are three times as high as among white persons, and the race-sex specific

Figure 4. Reported cases of syphilis and gonorrhea, by race and sex, continental United States, fiscal year 1951 (known military cases excluded).

Figure 5. Reported cases of acquired syphilis, by race and sex, by stage, continental United States, fiscal year 1951 (known military cases excluded).

rates per 100,000 population are 65.6 for white males, 29.5 for white females, 1,900.9 for nonwhite males, and 688.9 for nonwhite females.

Congenital Syphilis

Congenital syphilis morbidity has not shown a downward trend during

the past few years such as has been shown by all other stages of syphilis. Interpretation of this sustained volume of cases reported depends on more complete information, particularly as to age of the infected persons which indicates the duration of the disease. Only recently have such

data been obtained. The following age distribution was noted for the continental United States in the fiscal year 1951:

Known age:	Number	Percent
Under 1 year-----	715	6.4
1-4 years-----	812	7.2
5-9 years-----	1,928	17.1
Under 10, age unknown-----	35	.3
10 years and over--	7,759	69.0
Total-----	11,249	100.0
Unknown age-----	1,587	
Grand total-----	12,836	

Ninety-four percent of the congenital syphilis cases were in persons 1 year of age and over. These represent past case-finding failure as well as present success. Whether the number of cases actually occurring or the fraction of undiscovered cases of congenital syphilis occurring each year is decreasing is a problem to be solved by detailed age data over a period of several years.

Synthetic Vitamin B⁶

Success in the synthetic production of vitamin B₆ in its pure form, was recently announced by the Public Health Service.

In the laboratory of biochemistry, at the National Cancer Institute, Drs. Alton Meister, Elbert A. Peterson, and Herbert A. Sober have produced 1 gram of vitamin B₆, the amount required for the lifetime of one healthy individual. Their work was reported in the January issue of the *Journal of the American Chemical Society*. So potent is the vitamin that man's daily requirements have been estimated to be approximately 2 milligrams—about $\frac{1}{15,000}$ of an ounce.

Only crude preparations of vitamin B₆ have been available in the past, and these could only be used in experimental studies. Publication of the new synthesis method will make possible large-scale production of the vitamin.

Anemia in cats and dogs results from the lack of B₆. If the vitamin is missing in rats, the deficiency is known as acrodynia.

The human body also needs vitamin B₆, which is present in meat, cereals, and yeast. Lack of this dietary essential prevents the body from making proper use of amino acids. It is known that cancer tissue contains a low level of vitamin B₆ and that its way of using amino acids differs from that of normal tissue.

Ideas

How do you go about getting your job done in health department, hospital, school? Are the ways you go about solving your problems likely to interest others who have similar problems? This "Ideas" section is a place for you to share with your colleagues your experience and approaches to the practical problems of public health practice. The "Ideas" space is not for news reports but for ways and means, a place to report trials and errors in techniques and methods. Send your ideas to us now! —The Editors.

Boarding Homes

MINNEAPOLIS. Elderly residents of boarding homes are meeting weekly to enjoy "purposeful activities" as well as to participate in recreational and entertainment sessions.

Under guidance of the Family and Children's Service, the group sessions were initiated by a professional social worker and later carried on under volunteer leaders who have been given special training for this work. The aim is to help older folks living in boarding homes to have more worth-while and interesting lives.

More than half the 104 residents now in the program have no other activity. They come from all walks of life and seem to be more handicapped physically, mentally, and emotionally than the average older person.

Departmental Diary

BUFFALO. Each Friday morning the elected and administrative officials of Erie County (N. Y.), as well as leaders of community organizations, the board of health, members of the health department staff, and press, radio, and television representatives receive *Health Notes*, a

single-sheet report of Erie County's health week.

Here—in one-paragraph, easy-to-read items—are reported the activities of the department and health events in the community, plus a health education item aimed at the individual and current morbidity data for half-a-dozen acute communicable diseases.

Health Notes is reproduced in typescript via a direct-plate office offset process on a pre-run masthead in red ink which carries the necessary postal designation. The address is stamped on the sheet itself, which is sealed with a 1-cent, precancelled stamp.

Disease Detection

FLORIDA. Screening for six major diseases—cancer, tuberculosis, diabetes, heart disease, blood diseases, and kidney diseases—is provided all patients entering the regular services of the Volusia County Health Department. Patients entering the cancer detection, maternity, and health card clinics receive the following: chest X-ray, physical examination, hemoglobin determination, blood count, blood sugar, RH (maternity), blood serology, urine analysis (sugar, albumin, specific gravity), stool examination (for food handlers and others as indicated), and smears for gonococci.

"Slide Rule"

WASHINGTON, D. C. A concerted effort to improve the reporting of "length of pregnancy in weeks" on the birth certificate has been undertaken cooperatively by the State health departments, the National Office of Vital Statistics of the Public Health Service, and the Children's Bureau of the Federal Security Agency.

Key element of the program is a "device for computing completed weeks of gestation." The device can be used continuously from year to year. It provides a systematic and quick method for obtaining the number of completed weeks between the first day of the mother's last menstrual period and the date of the

child's birth. Use of the device should reduce inaccuracies now found in reported information because of diversity of computing methods.

The device has been made available to hospitals throughout the country and may be obtained from State health departments, the National Office of Vital Statistics, or the Children's Bureau.

How to use this device to determine completed weeks of gestation for entry on birth certificate.

Handbooks on Sanitation

Since it is generally recognized that sound sanitation practices are an important factor in good service, and healthful, safe, and enjoyable travel is a product of good service, a series of handbooks has been prepared by the Division of Sanitation of the Public Health Service as a guide for persons responsible for maintaining sanitation facilities on interstate carriers. The standards set forth in each conform with the interstate quarantine regulations. Each booklet contains a copy of the Public Health Service report form.

Railroad Servicing Areas

The first handbook has been prepared for persons who design and operate railroad servicing equipment and facilities, and for health department representatives and others who make periodic investigations or inspections of facilities and operations in servicing areas. This publication covers general requirements and specifications for water equipment, employee conveniences, and waste disposal.

Dining Cars in Operation

Because of the large number of passengers carried on trains today, dining car sanitation is of public health importance. The second handbook is designed for those who must apply the principles of sanitation to dining car operation and maintenance. The standards set forth include not only those for sanitation of equipment, storage and handling of utensils, and disposal of waste, but those for floors, walls, doors and windows, lighting and ventilation of the car. Food handling, storage, and the protection of food are also covered.

Passenger Car Construction

The third of the handbooks on railroad sanitation outlines standards for those concerned with incorporating provisions for sanitary

equipment in the design or construction of passenger cars. General standards for water supply facilities, toilet and lavatory facilities, and ventilating and heating are outlined for passenger cars, coaches, sleeping cars, and dormitory cars. Specifications are given for facilities, ventilation, lighting, etc., for dining and bar cars, and for handling, storing, and protecting food in these cars.

Vessels in Operation

The last handbook listed here is the second of a series on vessel sanitation. It outlines standards for persons making inspections of operating vessels, and for those supervising sanitation facilities aboard vessels. The first handbook, "Principles of Sanitation Applicable to the Construction of New Vessels," appeared in 1949. The new booklet covers potable water, wash water, swimming pools, waste disposal, vermin control, food sanitation, and rat-proofing.

Handbook on Sanitation of Railroad Servicing Areas. (Public Health Service Publication No. 66) 1951. 28 pages; illustrated. Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. 20 cents.

Survey of Compounds Tested For Carcinogenic Activity

The first edition of this "Survey" covered the literature on experimental carcinogenesis through 1939. The present (second) edition brings the material up to 1947. It lists 1,329 compounds, of which 322 were reported to cause malignant tumors in animals and 35 others to induce only benign tumors.

What You Should Know About Alcoholism

Prepared for the general reader, this nontechnical publication defines alcoholism and the alcoholic. The symptoms and causes of alcoholism, as far as they are known are outlined. Of importance to the lay reader are the sections on understanding and helping the alcoholic. Here the role of friends and members of the family, and local health and welfare agencies are described.

The sections on treatment include the physical build-up that is usually necessary, drug treatment, and psychiatric care. The work of organizations especially devoted to this field—Alcoholics Anonymous, the National Committee on Alcoholism, the Yale University Laboratory of Applied Physiology, the Yale Center of Alcohol Studies and the National Institute of Mental Health—is briefly covered.

Suggested sources of information, books, and other publications are listed at the end of the pamphlet.

Recent Trends in Meningococcal Disease

By ARTHUR W. HEDRICH, Sc.D

The incidence and mortality of meningococcal disease have been slowly rising after a 5-year decline from the 1943-44 epidemic.

Another trend observed in the civilian population is the appreciable rise in the apparent case fatality. Since modern therapy should have reduced the ratio of deaths to recorded cases, indications are that case reporting has deteriorated in recent years.

Data are given here to support these observations, to aid in gauging epidemic potential, and particularly to indicate population segments which appear to be at especial risk.

General Epidemiological Characteristics

The term "meningococcal disease," used at times in this report, includes various clinical forms of the infection, such as meningitis, meningococcemia, and milder forms of invasion.

Bacteriological Types

The bacteriology of the meningococcus is complex, and classifications and viewpoints have changed considerably. The many different strains of the organism are now commonly classed into three major groups. Type I apparently predominates during heavy epidemics, and types II and IIA, endemically (3a, 16). This raises the question whether publication of current national summaries of types found in

State and local diagnostic laboratories might be of value to epidemiologists during the present rising phase of the disease.

Perry (15) advises that in Maryland too few specimens are offered nowadays for diagnostic purposes. However, all of the 14 positives received from 1942-46 (including the epidemic) were type I; of the 7 positives received subsequently (1947-51), only 1 was type I; 3 were type II, and 3 were type IIA.

Clinical Types and Carriers

Three clinical stages of the disease are: (a) nasopharyngeal infection, which is normally asymptomatic and extremely difficult to detect; (b) invasion of the blood stream (septicemia); and (c) meningitis. The nasopharyngeal infections, although unquestionably the major source of new cases, are rarely recorded. Practically all of the reported cases are septicemias and meningitis.

Nasopharyngeal infections are extremely common during epidemics. In Army camps, prevalence of asymptomatic carriers may run from 30 to 50 percent or more of the strength (2, 3, 6); and even in civilian communities prevalence of meningococcal carriers has been found to be as high as 30 percent. This means that meningococcal infection during epidemics may be about as prevalent as the common cold. Hence, it has been said that "the recognized cases constitute merely the visible foam on top a huge carrier wave" (6). Even during endemic periods in the civilian population, meningococci may be found in the rhinopharynx in about 2 percent of the healthy persons.

It has been estimated that possibly as few as 1 per 1,000 subclinical infections develop into

Dr. Hedrich is chief of the division of vital records and statistics, Maryland State Department of Health, and lecturer in vital statistics at the School of Hygiene and Public Health, The Johns Hopkins University.

frank cases with septicemia or meningitis (1, 7b).

Fulminating Cases

Although the sulfa drugs and antibiotics have been effective therapeutic agents, the following recent incidents among others (3, 14) illustrate the problem of obtaining prompt diagnosis and treatment in fulminating cases.

1. Dr. A. L. Gray, Mississippi State Board of Health, recently reported (12a) four deaths from meningococcal disease within about a month among Negroes in a rural neighborhood. Duration of illness was 8 to 16 hours. One death certificate gave "bronchial pneumonia" as the cause of death, but on autopsy this was changed to meningococcal septicemia. A second death certificate reported "no doctor."

2. Dr. James Strain advises the writer that during his 2-year residency in Cleveland hospitals in 1948-49, some 8 to 10 children with previous diagnoses of measles, then heavily prevalent in the city, arrived at the emergency wards in moribund condition or dead. Post-mortem blood cultures in these cases revealed meningococci.

Age, Race, and Sex

The reported case rate for infants is four or more times higher than for school children and adults (table 1 and fig. 1). In measles the opposite is true, the attack rate at ages 6 and 7 being fully four times higher than in infancy (3).

Figure 1. Reported case and death rates for meningococcal meningitis by age, Maryland 1940-49.

Obviously, some form of immunity to effective meningococcal invasion is commonly developed early in life.

At ages 15-24, the hump seen in the case rate curve of figure 1 is probably attributable mainly to the excess of cases reported from Maryland induction camps during World War II. Other data (14), however, indicate that during epidemics the attack rate among adults in Maryland is generally stepped up from 3 to 10 times more sharply than the rate for infants. In other words, although infants are always the most vulnerable group, in epidemic periods adults have the highest increase in reported case rates.

The apparent case fatality (ratio of deaths to reported cases) during a 10-year period is

Table 1. Age distribution of morbidity, mortality, and apparent case fatality for meningococcal meningitis, Maryland 1940-49

¹ Apparent case fatality is the ratio of deaths to reported cases.

relatively high in infancy and in late life, and lowest in the second and third decades of life (fig. 2 and table 1).

Data from an unpublished thesis of J. H. Fan (10, 14) indicated that during 1930-41: (a) males had about double the attack rate of females, the excess being slightly greater in Baltimore City than in the counties; and (b) the attack rate among Negroes in Baltimore City was about 3.7 times as high as the rate for white persons. In the counties of Maryland, it was only about 2.1 times as high. The correlation of high attack rates with crowding suggests that congested living conditions may be primarily responsible for the high attack rate among the Negroes.

Role of Population Crowding

It has long been recognized that meningitis spreads most rapidly at times and places of population congestion, where contact rates are high, as in war camps and institutions. Military authorities found in World War I that increasing the space between beds in barracks decreased the meningitis attack rate (6).

In Baltimore City, attack rates in the most crowded areas averaged about seven times the rates in the least crowded during two epidemics (fig. 3 and table 2). In fact, during the 1935-37 epidemic, this ratio of attack rates of crowded/uncrowded was 12.5.

Figure 2. Apparent case fatality for meningococcal meningitis by age, Maryland 1940-49.

Rural areas also showed low rates. In 1942, the latest epidemic year Fan (10) could include in his study, the incidence rate for meningitis was only 5.0 per 100,000 population in the 9 counties with less than 60 persons per square mile, compared with a rate of 12.7 for suburban districts of Baltimore, and 23.1 for "Old Baltimore City" which has 26,000 persons per square mile.

It is important to recognize that in Maryland, at least, the excess risk for the city applied especially to epidemic periods. Table 3 shows that although, during recent epidemic periods, the death rates in Baltimore averaged 2.6 times more than the rates for the rest of Maryland,

¹ Death rates are per 100,000 person-years.

during recent low-incidence periods the city rates have averaged only 0.86 as high as the counties. A somewhat similar decline in the city/county ratio of death rates was noted in New York State (11).

Epidemic Cycles

The rise and fall of death rates from meningococcal disease in the United States since 1915 are shown in figure 4. The underlying annual data for the last two decades are shown in table 5; and data for the earlier years are from Gover and Jackson's tabulations of cerebrospinal meningitis (5b). Figure 4 indicates that:

1. Of the four epidemic crests, two came during war periods (1918 and 1942-43) and two came during periods of relatively high industrial activity during peacetime (1929 and 1935-36). In other words, all four epidemics came during periods of high travel rates and movement of population from rural to more congested areas, such as war camps and cities.

2. The inter-epidemic intervals have varied. Two were of 7 years' duration, and one was 12 years. Observations over a longer time (5, 7) indicate that the interval between epidemic peaks, while varying from a few to as many as 20 years, has averaged about 8 years.

3. During the past 36 years, the national epidemic waves have had a marked continuity and

orderliness. When the annual death rate began to rise, the wave continued rather smoothly to its peak with one minor exception (1933). The declines, likewise, tended to proceed systematically from peak to trough of the wave. For

Figure 3. Relation of population congestion to reported meningococcal meningitis morbidity, Baltimore, Md. (epidemic periods 1935-37 and 1941-42).

smaller areas or monthly time intervals, the numbers are smaller and the waves correspondingly less systematic (5a).

Earlier studies (5, 7) have shown that the epidemics in the several regions of the United States tended to synchronize with the national curve, although there were frequent deviations in peaks of a year or two. This geographic

Figure 4. Annual death rates for meningococcal meningitis in the United States, 1915-51.

synchronism has been especially strong during the wartime epidemics, when large numbers of men went to military camps at about the same time. It has further been observed that regions which had very high rates in one epidemic tended to have lower than average rates in the next, and vice versa (7a).

4. In meningococcal disease, the rise to the epidemic peak is more deliberate than for most other communicable diseases, for example, influenza. Examination of regional data for the last 3 epidemics shows that of 27 ascending episodes within regions, the interval from trough to crest was about 3 years in 14 ascents, or slightly more than half. In seven ascents, the duration was about 2 years; in four, it was 4 years; and in two ascents, it was apparently 5 years (5a).

5. The most recent low point in mortality for the United States occurred in 1949; but there has been a rather flat trough during the last 4 years which resembles the wave bottom which terminated the recession from the World War I epidemic wave. The rise following that trough covered fully 4 years: from 1925 to 1929. If history should repeat itself in this regard, several years of increase would lie ahead.

Quarterly Index of Epidemicity Trend

To give a more detailed view of the recent rise and to facilitate projection into 1952, quar-

terly morbidity data are given in figure 5 and table 4. Like most communicable diseases, meningococcal infections show a seasonal cycle in which, from the low in about September to the high point in early spring, cases are multiplied on the average by about four—sometimes more during epidemics (5c). In order to cancel out this seasonal swing and to show an epidemic wave comparable with the annual data, an "epidemicity index" has been calculated for each quarter year. This index is the ratio of reported cases to the median of the corresponding quarters for the 10-year period 1940-49.

Comparison of the epidemicity index (fig. 5)

¹ Quarterly reported cases received from National Office of Vital Statistics.

² The median is a mid-point above and below which half of the experience tends to fall. To reduce the effect of erratic fluctuations, medians were taken as the geometric mean of the four middle items in each quarterly array. (A geometric mean locates the median position more dependably than does an arithmetic mean in epidemic series.) A 10-year span (1940-49) was taken in calculating the quarterly medians instead of the more conventional 5-year span so as to include approximately one entire epidemic wave. For a disease with a long cycle, the 5-year span tends to give relatively high medians near epidemic peaks and low ones near the trough. This may distort the epidemicity index somewhat. The philosophy behind the ratio of current cases to median cases as an "epidemicity index" has been discussed previously (9).

with the corresponding wave of the annual mortality rates (fig. 4) shows that the two are nearly parallel, indicating that the quarterly

index yielded about the same shape of epidemic wave as the annual data. The quarterly index as shown on the graph and in table 4 indicates that:

1. During the 1943 epidemic, reported cases rose to about six times the 10-year medians for corresponding quarters.

2. At the end of the subsequent 5-year decline, the national cases dropped to a low of 0.73 of the median in the fourth quarter of 1947, and since that time the cases have gradually risen to, or slightly above, the median values during most of 1951.

3. For Maryland, the epidemicity index showed about the same wave as the United States although, largely because of smaller numbers, the Maryland curve fluctuated more violently (14).

4. On the basis of reports (12b) to the week ending March 29, 1952, it is estimated that the reported cases for the United States during the first quarter of 1952 equalled 1,685. The median expectancy for the quarter being 1,384, there results for the first quarter an estimated index of epidemicity of 1.22, compared with 1.01 for the previous quarter. The index has, therefore, risen considerably higher in 1952 than is suggested by the conservative estimate shown in figure 5, prepared early in March.

Army vs. Civilian Morbidity and Mortality

From 1930 to 1951, the reported Army meningitis cases generally exceeded civilian cases considerably. The excess Army morbidity was highest at times of heavy induction or discharge of forces and lowest during periods of relatively stable strength. Sartwell and Smith (4), Thomas (3a), and others have reported that meningitis rates among recruits are highest within a few months after induction.

That the rise and fall of meningitis in the Army is strongly influenced by inductions and discharges is indicated in table 5 and figure 6:

1. The Army morbidity rate was below the civilian rate in but one year, 1933—a period when the armed forces were apparently stabilized at a fairly low level (table 5, last column).

2. Morbidity increased to epidemic peaks in 1935-37 and 1943, when Army rates were four to eight times the civilian rates. These increases in morbidity were approximately, though not exactly, coincident with heavy inductions into the armed forces. From mid-year 1940 to 1941, for example, Army strength was multiplied by 5.5.

3. The unexpected rise of Army rates in 1946 to about 10 times the civilian rates is associated with a period of rapid demobilization. June 30 Army strength declined from 8.2 million to 1.9 million in less than one year, with consequent congestion of travel facilities and separation centers.

4. The morbidity increase in 1951 was concurrent with mobilization for Korea.

In comparing military with civilian morbidity statistics, one must note the difference in reporting. Case diagnosis and reporting is usually more thorough in the military than in the civilian population. On the other hand, civilian statistics are expanded in the young adult ages by the more complete reporting to civil health authorities of cases from local Army camps.

Army mortality was about equal to the civilian mortality rate in the early 1930's, but it rose much higher during periods of appreciable induction or demobilization of personnel and declined toward the civilian rate during periods of strength stability. The effect of the newer therapies has been apparent during the past 8 or 10 years. The Army death rate nearly

ACKNOWLEDGMENTS

In the preparation of this report, cooperation was received from many different sources. The writer is particularly indebted to the following: Dr. James Strain, for his review of recent literature; Dr. Dean Roberts, deputy director of the Department of Health, for making this report possible and for helpful suggestions; Drs. Kenneth F. Maxcy and Philip E. Sartwell and their associates in the department of epidemiology at the School of Hygiene and Public Health of The Johns Hopkins University, who arranged for a discussion seminar; Dr. Fan, for the loan of his unpublished thesis (10)—because of communication difficulties, Dr. Fan's personal approval of publication was not obtainable; Dr. John Phair, for the loan of an unpublished manuscript; the offices of the Surgeons General of the Army, Navy, and Public Health Service, for unpublished statistics; and, to the various members of the Maryland State Department of Health, for their valuable assistance.

The Total Patient-Care Approach To Chronic Disease

By JOSEPH F. FAZEKAS, M.D.

Chronic diseases are not limited to older persons. Yet, because they are, by and large, more common in older people, the care of patients with chronic disease and disability is the foremost medical problem in our aging population.

The annual frequency of disabling chronic cases among the age groups 65-74 and 75 and over is three to four times that among the population at large. Illness among the aged also lasts longer than among the population as a whole.

The real need for an organized community program to aid elderly patients who have chronic medical conditions is shown by the increasing numbers vegetating in "convalescent homes," occupying hospital beds, or simply on public assistance rolls. These people constitute a financial drain upon others as well as a great waste of potential human resources.

Since the community suffers a double loss, it has the responsibility both of preventing and of finding a remedy for the problems of chronically ill people. Admittedly, many of them cannot be restored to any kind of productive activity. Nevertheless, even more chronically ill persons are being consigned unnecessarily to a helpless existence.

The Goal of Total Patient Care

The purpose of a total program for the management of patients with chronic disabilities should be to restore them to a state of optimum

usefulness in society. The problem is economic and social as well as medical. All therapeutic facilities should be available to these patients, but they may also need at least minimum financial assistance to provide for the necessities of life and for those other requirements (such as transportation to treatment areas, pharmaceuticals, and appliances) imposed by age, disease, or disability. This assistance should not be limited to indigent citizens. Persons of our so-called middle class should be qualified to receive treatment in all phases of the program without exorbitant expense. Otherwise they may forego needed rehabilitative services until it is too late.

If total patient care is to be effective, educational programs for various professional and lay groups as well as for patients must be undertaken. In our medical schools, undergraduate instruction should emphasize the importance of economic and social factors in the management of chronic diseases. Physicians would then not be completely absorbed with the diagnosis and treatment of disease entities. The public should be informed of the importance of early detection and treatment of all chronic diseases, and particularly those so frequently encountered in old age. Families must again realize that they have a certain responsibility for the care of their chronically ill members.

Moreover, all patients with a chronic disease should receive specific instructions regarding their illness, to prevent exacerbations and to delay progression as much as possible. In many cases, group educational therapy would be of great value in promoting improved self-care of patients who have the more common chronic diseases such as obesity, diabetes mellitus, peripheral vascular disease, and chronic cardiac

Dr. Fazekas is chief of staff at Gallinger Municipal Hospital, Washington, D. C.

disease. The community as a whole should be taught the necessity of providing for rehabilitation. Finally, industry should be informed about the excellent work potentialities of rehabilitated persons, and its fears about employing them should be allayed.

The development of an effective program for the management of chronically ill persons would require little more than the expansion and integration of existing community facilities. The total patient-care approach, however, will never be achieved unless these facilities are organized into a coordinated unit. The various health department bureaus would function more efficiently and economically if they were combined in a direct medical service unit, just as would all direct medical services if they were part of a hospital unit. With such an integrated organization, medical school curriculums could provide experience in care of patients both within the hospital proper and in all branches of medical care that the student may encounter after graduation. In addition, the practicing physician could make better use of community facilities if auxiliary services were more accessible to him. The specific needs of his patients, whether they were early case finding, continued medical supervision, occupational therapy, vocational selection, or home care, would be more efficiently satisfied. Some of these needs are discussed below as facets of a total program.

Case Finding and Selection

The identification of disease stages after the appearance of symptoms is manifestly less satisfactory than the detection of early asymptomatic cases. In the latter, hospital treatment is still unnecessary and the patient is able to earn his own way. This is particularly true of the many chronic diseases frequently found in the elderly population, and which are usually diagnosed and treated only when hospitalization becomes necessary.

Different methods of early case finding and selection have been tried throughout the country. There have been large and successful detection drives for tuberculosis, venereal disease, and diabetes mellitus. Usually these have been limited to laboratory and X-ray procedures and by no means are intended to take the place of a

thorough physical examination by a physician, plus diagnostic tests.

Because of some doubt as to the efficiency of organizing separate campaigns for each disease, the concept of the "multiphasic screening line" has developed. This is designed to detect early evidence of a large number of common chronic diseases in a single short visit to a detection center. Many communities will probably establish such facilities permanently because they can be operated with a minimum of administrative expense and inconvenience to the individual.

In a total care program, definitive diagnosis of actually or potentially disabling chronic disease should be made by private physicians, by ambulatory diagnostic clinics of hospital outpatient departments, and occasionally by the hospital itself. Many patients would be referred from screening lines to these facilities for full investigation of abnormal findings, others would seek medical attention because of symptoms related to their chronic diseases or to incidental illnesses. Definitive diagnosis would disclose two large categories of incapacitating illness: those which are amenable to treatment and can be arrested, and those which are inexorably progressive. Nothing need be said here about those persons afflicted with a disease which can be completely arrested with adequate therapy before disability occurs. Patients for a total care program should be selected because of the presence of residual handicaps after arrest of a disease process or because of the probability of the appearance of varying degrees of incapacity.

Medical Care

Once a definitive diagnosis has been made, the nature of further medical attention should depend upon the patient's particular disease state, the source of his care, and his financial limitations. Uninterrupted medical supervision is absolutely necessary for the prevention or amelioration of exacerbations. The present tendency toward providing care only when exacerbations become severe enough must be reversed.

When the patient's financial status permits, medical care should be provided from the out-

set by a private physician. If the patient is indigent, out-patient clinics, held in the evening as well as in the daytime, should be available. When distance or the patient's disability makes these clinics inaccessible, the medically indigent must be transported to them or be given domiciliary care.

Rehabilitation

Many people can meet the costs of medical supervision alone; relatively few can afford to pay for the ancillary services which are so necessary for complete rehabilitation. Deprived of these facilities, people continue at their usual occupations as long as their physical condition permits. Then, depleted of their resources, they become completely dependent upon relatives or the community.

Rehabilitation efforts should supplement the medical treatment of chronic disease in such a way as to restore or maintain to the optimum degree the individual's physical and mental state and his usefulness to society and himself. Whenever possible, these efforts should anticipate the actual need and be instituted before incapacity has appeared. The physician should direct the rehabilitation program, but he cannot provide his patients with physical, occupational, and vocational therapy, find them suitable positions, or provide assistance for their dependents during the period of readjustment.

Many of the ancillary services needed by patients with chronic disease already exist in individual private organizations. Because of their cost, however, they are not all available to the average patient. The community cannot establish competitive services, neither can it afford to let its needy members suffer. The most reasonable solution to the problem would be the establishment of a community rehabilitation center to which physicians could refer patients for any ancillary services required. The center could be financed by both the community and the individual with the latter contributing a proportion of the service costs according to his financial status. It would aim, not to provide permanent care, but to enable chronically disabled patients to care for and maintain themselves as long as possible. Thus it would give the middle-income groups some protection

against the prospect of inadequate support for an indefinite period. Some of the services that would be helpful to the practicing physician which could be provided in the rehabilitation center follow.

Physical Therapy

If an incapacitated person is given physical therapy, it may prevent further deterioration and restore function to such a degree that he will not have to change his occupation. When this frequently difficult change of occupation is necessary, the patient's residual physical abilities should be preserved and improved in order to provide the largest possible range of vocational choice and the basis for maximum proficiency in whatever he does.

The paucity of good physical therapy services in most communities is due to limitations of floor space in appropriate institutions, to lack of properly trained personnel, or to the high initial outlay these services require. A community health center or hospital is the logical site for the bulky and expensive equipment used in physical therapy, so necessary for the ambulatory treatment of many chronic disease patients.

Vocational Selection and Training

It is necessary to determine the patient's optimal occupation and to train him for it. His choice of work should be dictated by his physical and mental capacities, his personal preference, and the financial opportunity available in his preferred line of endeavor. In any occupational planning program, local employment needs should be constantly surveyed so that jobs selected will be important and useful.

Occupational training should be available to those patients whose age and physical disabilities require that they change jobs. In a large proportion of cases, vocational training will include occupational therapy; in all cases, its goal should be self-support. Training eventually may provide financial independence and also improve physical status by strengthening muscles, improving coordination, and increasing joint range. Where supervised graded training in selected vocations is available, there should

be sheltered workshops for the more severely disabled patients in the community center.

Laboratory Services

A well-equipped laboratory offering complete clinical studies at reasonable cost would be invaluable to the care of the middle-income, chronically ill patient. Physicians know well that much of the cost of good patient care is due to the many laboratory studies often essential for a complete diagnostic work-up. The indigent patient receives such services at community expense. The patient in the middle-income range can usually afford them during an acute illness, but their cost is prohibitive during continued control of chronic illness.

Research

Much research will be required to establish criteria by which those persons most suited for the services of a total rehabilitation program can best be selected. The cost of rehabilitation is unquestionably increased by inaccurate estimates of the work tolerance and capacity of patients with chronic disease and the time needed to help them. Inevitably, many patients are carefully treated and trained only to deteriorate, perhaps to such an extent that rehabilitation efforts fail. The community center is the logical site for research in these efforts, for the development of more efficient physiological methods which improve function, and for devising better prostheses and appliances.

Hospital Care

Hospital care is often necessary for chronic disease patients, who in fact, now occupy most of the hospital beds. Some need it because of an acute onset heralding illness, most others because of exacerbations of the disease process, or incidental accident or sickness. For still other patients, definitive diagnosis will require short initial hospitalization.

Nevertheless, making more hospital beds available to patients with chronic diseases is not the best solution of the problem. Most hospitals are still mainly geared for acute medical and surgical disturbances. Too often, for the pa-

tient with a chronic illness, they are unnecessary and expensive—in fact, nothing more than places of residence. Moreover, the inactivity and isolation imposed by a prolonged institutional existence often causes further physical and psychological deterioration. Once families and physicians have disposed of their obligations, they are often reluctant to reaccept responsibility for continued care, and the patient may find it difficult to adjust to a home atmosphere filled with resentment.

When hospitalization is specifically required, chronically ill patients may be referred to private institutions or to community hospitals. Treatment of acute medical and surgical conditions should be followed by transfer to convalescent wards, where active rehabilitation can be instituted or continued. Such facilities would greatly reduce community costs through reductions in nursing personnel and because patients could perform a large proportion of the maintenance work. Some physicians could attend acute medical and surgical cases. Other physicians could give their entire attention to the care and rehabilitation of patients convalescing from exacerbations of chronic disease. Relieved from other duties, the physician would be less likely to ignore the chronically ill patient for "the interesting case in the next bed."

Concentrated efforts toward the rehabilitation of some convalescent patients should significantly shorten their hospital stays. Once they are self-sufficient, they can be discharged to their homes and referred to the community rehabilitation center, where rehabilitative efforts can be continued.

Home Care

The home care medical program, which has been for the most part restricted to the indigent population, has been demonstrated to be of great value to both the patient and the community. It gives the patient the opportunity to remain in the family environment even though he may be totally incapacitated, thus providing the psychological drive so important for the optimum degree of recovery. It protects him, too, from the physical and emotional deterioration so frequently associated with long periods of hospital

confinement. It shifts the responsibility for his care back from the community to the family, which is often willing and able to assume the responsibility if given the necessary technical assistance.

The cost of home care for an individual patient is about one-quarter the cost of hospital care. Home care, too, leaves badly needed beds available for "acute" cases. It should not be restricted to the indigent. There is no reason why private patients cannot remain under the complete supervision of their physicians at home while receiving the ancillary services provided by home care technique.

Terminal Medical Care

There will always be patients who do not respond to rehabilitation efforts, either because of the nature of their disease or because the dis-

ease is in a terminal phase. These patients should be cared for in separate quarters if they cannot be kept at home or in supervised nursing homes.

Conclusion

The adoption of the concept of total patient care and its application to the various phases of the management of chronic disease is basic to the formulation of a chronic disease program. The success of any such program will depend upon the coordinated efforts and leadership of medical societies, medical schools, and community health officials. When the entire community is conscious of the chronic disease problem and all its existing facilities are integrated and working for total patient care, its responsibilities to patients can be more satisfactorily discharged.

Dr. Joseph W. Mountin, Pioneer in Public Health, 1891-1952

Dr. Joseph W. Mountin, Assistant Surgeon General and Chief of the Bureau of State Services of the Public Health Service, died unexpectedly April 26, 1952, at the age of 61. A Public Health Service officer for 35 years, Dr. Mountin was appointed to the post of Bureau chief November 1, 1951.

Dr. Mountin had a distinguished career with the Public Health Service and was widely known as the "father" of many Service programs.

He was a special health adviser to the Bhore Commission for the Government of India in 1947. During 1949, he was adviser on health and welfare to the Economic Mission to Colombia, South America, sponsored by the International Bank for Reconstruction and Development. At the time of his death, he was Public Health Service director of the evaluation of the 10-year health and sanitation program of the Institute of Inter-American Affairs.

The author of numerous studies and monographs on preventive medicine, public health administration, and medical care, Dr. Mountin was a diplomate of the American Board of Preventive Medicine and Public Health and a fellow of the

American Medical Association. He was a fellow of the American Public Health Association and a member of its Executive Board. He was also a member of the Board of the National Organization of Public Health Nursing and had served on many official committees of other health organizations.

He was known as an authority in a wide range of public health fields from environmental health programs, such as sanitation, water pollution control and industrial hygiene, to public health nursing, public health education, the control of chronic diseases, and problems of the aging.

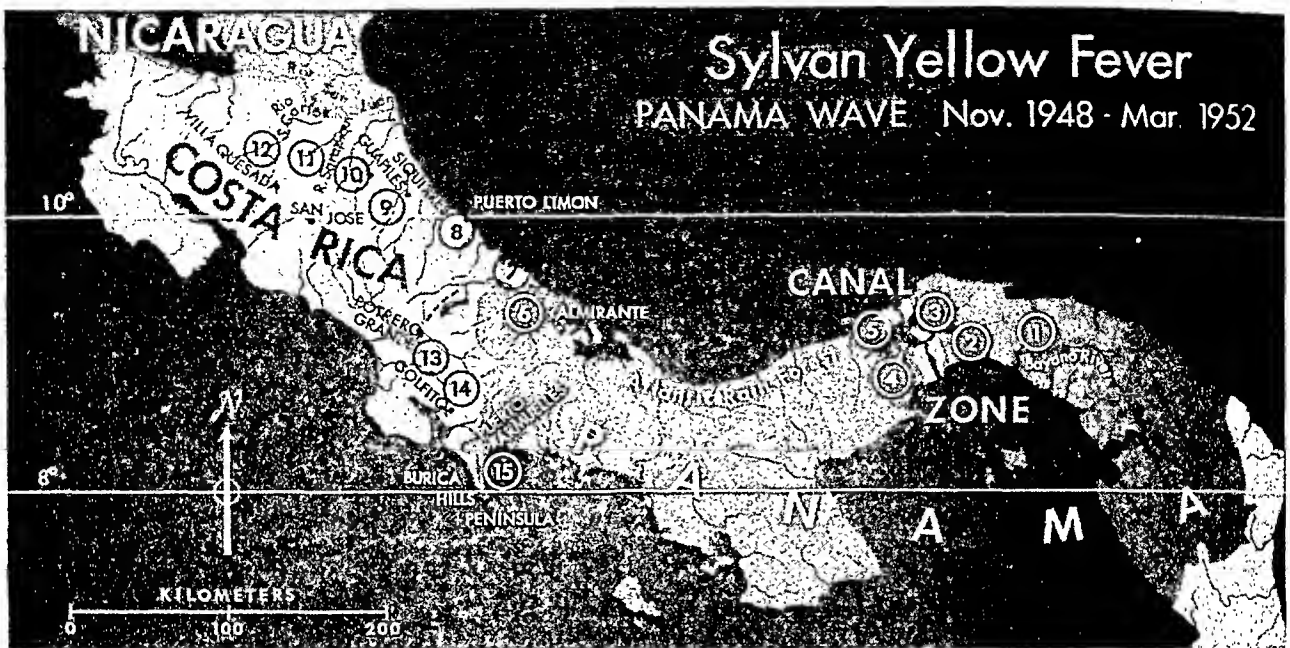

Dr. Mountin was born in Hartford, Wisconsin, and received his medical degree from Marquette University, Milwaukee, in 1914.

He began his career with the Public Health Service during World War I in work in extracantonment sanitation in military areas throughout the United States. He was director of the Division of Public Health Methods from 1937 to 1939 and of the States Relations Division from 1943 to 1947, when he became associate chief of the Bureau of State Services.

"Dr. Mountin was one of the real pioneers of public health in modern times. He was a man of rare gifts, of many skills, of much imagination who, throughout his long and distinguished career, provided the spark for many of the major programs of the Public Health Service and the public health movement. His wisdom, his progressive leadership, and his warm and sympathetic understanding of medical and health problems will be widely missed. His passing is a great loss to the Service and to the public health profession in the United States and throughout the world."

—LEONARD A. SCHEELE, M.D.

Sylvan Yellow Fever

in

Central America

By NORMAN W. ELTON, M.D.

A dramatic episode in the history of medicine is now being enacted in Central America. A wave of jungle yellow fever has moved from the long-established enzootic region of eastern Panama to the forested plains of northern Costa Rica, progressing some 450 miles since November 1948. In its wake it has left 41 proved human fatalities among the farming population, 8 in Panama and 33 in Costa Rica. Complete autopsies have been performed and the

cause of death confirmed by several laboratories.

The velocity of this wave is only 12 to 15 miles per month, following a pathway delineated by forest continuity, tree-top mosquitoes, and arboreal mammals (especially the primates). Although advance areas in its projected path have been repeatedly alerted to anticipate its arrival—since the recognition of its existence as a wave in January 1950—sporadic cases and epidemic outbreaks have continued to occur in spite of control measures.

Colonel Elton is a U. S. Army medical officer on duty with the Governor, Canal Zone Government. He is director of the Board of Health Laboratory at Ancon.

The wave appears to move in halts, by insidious infiltration, and in bursts, depending on natural conditions. Although their nature is still poorly understood, these movements are undoubtedly based on population density and

Epidemic Centers and the Path of the Wave

The valley of the Bayano River ① and the region east of it have been recognized as an enzootic area for sylvan (jungle) yellow fever since 1929 (see map).

The Pacora area ② in November and December 1948 was the site of five fatalities among the farming population. These deaths may have been due to yellow fever. Histologic examination of the liver proved yellow fever to be the cause of death in two cases; in two others no liver tissue was saved for histologic study; and the remaining case exhibited an atypical liver lesion which was not diagnostic.

In August and September 1949, while it was still not realized that a yellow fever wave was in progress, three fatalities in which the typical liver lesion was confirmed occurred in the Buena Vista area ③.

In Gatun Lake, Barro Colorado Island ④, established in 1923 as a government reservation and wildlife preserve, is the home of about 30 clans of howling monkeys, which are particularly susceptible to yellow fever and suffer a high mortality. Early in 1951, studies indicated that some epizootic, probably shortly after the dry season of 1949 (January–April), materially reduced the population of these monkeys.

A human fatality from yellow fever occurred in the Chagres District ⑤ west of the Canal Zone on the Atlantic side in January 1950 and the pattern of the wave was recognized for the first time. Within 2 months the Minister of Public Health of Costa Rica was informed through diplomatic channels that the wave could be expected to reach Costa Rica in from 14 to 18 months. At the same time a fruit company subsidiary at Almirante ⑥ was alerted to watch for the wave after it had passed along the sparsely inhabited Atlantic rain forest.

Autopsy tissues, received in April 1951, confirmed the diagnosis of yellow fever in a chainman engaged in a highway survey in the forest about 10 kilometers west of Almirante. Within a week after this diagnosis was made, an intensive vaccination campaign was initiated in Costa Rica.

In June 1951, the virus of yellow fever was isolated from the serum of a patient admitted to the Almirante Hospital from a Costa Rican farm just across the border near Nivecita, Panama ⑦. This patient recovered.

Heralded by an initial fatality near Puerto Limón ⑧ on July 24, 1951, epidemic jungle yellow fever developed with explosive violence along a 100-mile front in North-

ern Costa Rica involving five epidemic centers ⑧ ⑨ ⑩ ⑪ ⑫ in rapid succession and almost simultaneously. These were as follows:

Epidemic center	Proved fatalities	Date of first and last fatalities
Puerto Limón-----	2	July 24; Aug. 1.
Pacuarito-Siquirres-----	3	Aug. 12; Aug. 20.
Roxana-Guapiles-----	3	July 27; Sept. 9.
Sarapiquí watershed----	19	Aug. 13; Sept. 30.
San Carlos watershed----	6	Aug. 19; October.

Early in October 1951 reports of the finding of many dead monkeys in the vicinity of Potrero Grande ⑬ were confirmed by the Director General of Public Health in Costa Rica. Panama was promptly informed. At the same time a serum specimen from a patient from this region, convalescing from clinically suspected yellow fever, reacted positively to the mouse protection test. Although skeptical about the significance of these findings, because of the high elevation of the continental divide in this region, an intensive revaccination campaign was immediately undertaken in western Panama on the Pacific side.

In January 1952, the Director of Public Health of the Republic of Panama was informed by Costa Rica that a mine laborer from the Coto District ⑭ had died in a Golfito hospital and a diagnosis of yellow fever had been histologically confirmed.

On February 10, 1952, a 23-year-old resident of the Burica Hills Peninsula died at a Puerto Armuelles hospital ⑮. This peninsula is hilly, forested, and populated by howling monkeys. The diagnosis of yellow fever was confirmed by two laboratories and the Armed Forces Institute of Pathology.

The probable location of the crossing of the continental divide is indicated by the arrow above Potrero Grande ⑯ where there is a heavily traveled trail leading from the Talamanca District on the Atlantic side to the valley of the Cabagra River on the Pacific side. Since the lowest elevation in the divide is between 5,000 and 7,000 feet at this point, it is considered likely that the virus was introduced, in May or June 1951, into the Pacific forest by a migrant farmer from the Atlantic side.

This offshoot of the main wave may move eastward after 2 or 3 months of rainy season (July–August 1952). It is now also moving northwest up the Pacific coast of Costa Rica as a secondary wave.

terrain and seasonal factors, as well as on the efficiency of vaccination campaigns. During the past 3 years the wave has swept successively westward across Panama and Costa Rica, and has crossed the continental divide to the Pacific side of southern Costa Rica, threatening to return eastward through the Pacific watershed of

Panama. There is no indication as yet that the main wave can be expected to stop until it reaches the forests of Vera Cruz and Tampico in Mexico.

At first glance the control of sylvan yellow fever seems simple, involving vaccination of the rural population as merely an administrative

matter. Experience has clearly demonstrated, however, that this is not easily accomplished. Although the Dakar (mouse brain) and 17 D (embryonated) yellow fever vaccines rank among the most efficient ever developed for the prevention of any disease, there are numerous factors that contribute to failure in the field. Improper storage of the vaccine may cause rapid loss of potency. The vaccine must be kept in a deep-freeze until issued for immediate use, for even while still within the ampule it cannot be expected to stand up under ordinary environmental temperatures longer than 1 or 2 weeks. When the ampule is opened, its contents must be used within an hour.

Swollen streams, muddy trails, dispersion of habitations, and even deliberate concealment of habitations in isolated regions contribute to the difficulty in gaining access to the farmers of the agricultural areas of the forest. Cooperation and understanding on the part of the farmers themselves is being obtained but is not yet fully achieved. Preliminary educational campaigns and the establishment of vaccination stations scheduled to open for operation on specified dates are necessary. Helicopters facilitate the reaching of isolated localities, and when the people are properly informed, their signal fires, spontaneously prepared when neighborhood groups assemble, attract the helicopter to unscheduled landings. The tremendous morale effect of the helicopter used for this purpose has been demonstrated in Costa Rica (3).

Complacency in yellow fever control would breed disaster for the farming population. Even in Costa Rica, where the epidemic was anticipated months in advance, the outbreak placed a severe strain on the facilities of the health department and the hospitals. Had the country not been prepared, the episode might have been a holocaust. Brazil, which has been working on the control of this disease since 1932, reported 400 deaths and more than 3,000 clinical cases in the recent great epidemic of 1950. Jungle yellow fever easily can be dangerously underestimated.

Epidemiology

Jungle yellow fever, except in its epidemiology, is the same disease as urban yellow fever.

In studies on the mosquito vectors of jungle yellow fever, human subjects are stationed on the forest floor and also on platforms in the canopy. The subject is placing a catching tube over a mosquito feeding on his arm. The ladder leads to a platform 45 feet up in the canopy where a second subject is making simultaneous catches (photograph by Dr. Harold Trapido).

It occurs, however, in rural areas, and involves mainly the farming population. In the Western Hemisphere it is known as "woodcutters' disease," since it is transmitted by the tree-hole-breeding mosquitoes of the forest canopy. These mosquitoes are most active around midday, and descend to ground level at the edge of the forest or in cultivated clearings, roadways, or riverways. Working in these clearings or felling trees to enlarge a farm are hazardous undertakings when the canopy mosquitoes are infected. One of the principal vectors in Brazil is *Haemagogus spegazzinii falco* Kumm, a tree-top mosquito, which has been found to be present in Panama and Costa Rica (7).

Until the discovery of jungle yellow fever in 1932 (16), the sylvan and urban forms were epidemiologically indistinguishable to histo-

rians. Reorientation is essential before proper historical interpretations can be made. Urban outbreaks have been known to originate, through a chain of infection, from the sylvan form of the disease: natives infected by the forest mosquitoes transmitted the infection to the *Aedes aegypti*, known since 1900 as the vector of the urban form. The reverse procedure might just as readily have originated sylvan outbreaks in the past, the disease being transmitted from urban foci in port settlements.

One of the transient reservoirs of the virus is known to be present in the arboreal primates (monkeys and marmosets), and such a reservoir may also exist to some extent in other arboreal mammals. Although certain species of the tree-top mosquitoes, such as *Haemagogus spe-*

gazzinii falco Kumm and *Aedes leucocelaenus*, are known to be vectors of the virus, other possible insect vectors are also being studied.

Sylvan yellow fever is primarily an enzootic or epizootic disease of the forest, with a high mortality for howling (*Alouatta*) monkeys. In fatal cases, these monkeys exhibit a liver and kidney pathology parallel to that found in rhesus monkeys and in man. During the recent outbreak of the disease in Costa Rica, specimens were studied from four howling monkeys, either shot or found recently dead. The kidneys exhibited a fully developed hemoglobinuric (lower nephron) nephrosis like that found in the human fatalities in Panama. The liver specimen from a monkey which was shot because it seemed ill exhibited the same type of convalescent yellow fever lesion encountered in rhesus monkeys during recovery after experimental infections. Of the other three liver specimens, two presented the classical, acute-phase liver lesion very much like that seen in man, and the third presented an acute lesion resembling that seen in experimentally infected rhesus monkeys. These diagnoses were made or confirmed at the laboratory of San Juan de Dios Hospital in San José, Costa Rica, and at the Board of Health Laboratory, Ancon, C. Z. The specimens are now among the accessions of the Armed Forces Institute of Pathology. The complete report on these wild "Vargas monkeys," in which the typical liver lesion of naturally acquired yellow fever has been observed, will be made at a later date.

Associated with the epizootic phase of jungle yellow fever, either simultaneously or lagging behind it by several weeks or months, is the epidemic phase involving the human population. That the epizootic phase is the precursor to the epidemic has long been known among the natives of Trinidad (13), and also in the lowlands of Guatemala (6). The howling monkey population in Brazil has been practically exterminated at times by waves of jungle yellow fever (12).

Pathological Anatomy and Clinical Pathology

During the westward passage of sylvan yellow fever across the Republic of Panama, complete autopsies were performed on the seven

Ladder and platform in the forest canopy where *Haemagogus* mosquitoes, vectors of jungle yellow fever, are caught as they attack human subjects. There are large seasonal fluctuations in the numbers of these mosquitoes. Long-term studies of them are being made by the Gorgas Memorial Laboratory in Panama and Central America (photograph by Dr. Harold Trapido).

proved fatalities from the disease. A complete autopsy also was performed on the most recent case occurring at Puerto Armuelles February 10, 1952. Three primary pathological processes appear to be involved in the mechanism of the disease, all of which may be considered interrelated: the hepatitis of yellow fever;

The black howling monkey, *Alouatta palliata aequatorialis*
Festa.

the hemorrhagic diathesis undoubtedly resulting from this hepatitis; and the hemoglobinuric (lower nephron) nephrosis as a sequel of the hemorrhagic diathesis. Clinically these processes appear as (a) jaundice, (b) hemorrhages from mucous membranes, such as the vomiting of blood, and (c) uremia, frequently manifest by terminal convulsions and coma.

The hepatitis of yellow fever is diagnostic of the disease and has been accepted as the basis for the recognition of fatalities from yellow fever since 1930. Recognition of its histological specificity has evolved gradually since 1890 (1, 2, 9, 11, 15).

That the acidophilic material in the hepatic necrosis can be cleared from the polygonal cells with rapid regeneration of the liver cords (1, 10) was again noted recently in a Panamanian dying on the ninth day of illness, indicating that the liver lesion is a transient phenomenon. During its presence, however, the hemorrhagic dia-

thesis develops to a degree indicative of a profound prothrombin deficiency (4) although this has not as yet been established clinically.

Among the hemorrhagic phenomena accompanying the liver damage are melena, hematuria, hematemesis, nasal and oral mucosal bleeding, cutaneous ecchymoses, hemorrhagic pneumonia, and hemoglobinuric (lower nephron) nephrosis (5, 8). The plugging of the tubules of the lower nephron by heme casts is a recognized phenomenon productive of uremia, and retention of nonprotein nitrogenous metabolites in yellow fever, due to hemorrhage, blood in the bowel, and the kidney damage, is not only to be expected but has already been demonstrated (14). This would lead to a state of uremia, with the typical oliguria, anuria, and termination in convulsions and coma encountered in the classical form of the disease. Occasionally a confluent bronchopneumonia is superimposed on the hemorrhagic reaction in the lung, as in two of the Panama cases.

Death can occur, then, in either of two phases: (a) from the liver damage before the hemoglobinuric nephrosis and uremia are fully developed; or (b) from uremia due to the hemoglobinuric nephrosis after the hepatic lesion has begun to undergo involution. Liver and kidney specimens studied from the Panama cases support this concept of the major clinical pathological mechanism in yellow fever. Clinicians have long been more concerned about the development of renal failure than with liver failure in the disease. This interpretation awaits confirmation or modification from analysis of the extensive laboratory studies performed in Costa Rica by the staff of San Juan de Dios Hospital in San José during the recent epidemic in that country.

Outlook for Central America

Time seems generously disposed toward all concerned with the current wave of sylvan yellow fever in Central America. Presently, the main front of the wave appears stalled in the valley of the San Juan River between Costa Rica and Nicaragua, and its progress, if any, is insidious. There is no evidence as yet of an epidemic in Nicaragua, or of sporadic cases there. During this respite, the Ministry of

Health of Nicaragua has vaccinated more than 112,000 persons in the threatened areas.

Sporadic cases have been reported from the Pacific side of Costa Rica, mainly from the Cabagra zone, in the southern part of Puntarenas Province, close to the Panama frontier. This region first came under suspicion in October 1951, when dead monkeys were reported near Potrero Grande. On January 15, 1952, a confirmed human fatality occurred after an in-

A new clearing in the otherwise unbroken rain forest northwest of Almirante, Bocas Del Toro Province, Panama, characteristic of the situation in which jungle yellow fever is contracted by humans. Two human cases occurred here in April 1951 in a group of men surveying a right-of-way through the forest for a projected road (photograph by Dr. Harold Trapido).

fection acquired in the Coto area, and on February 10 a resident of Burica Hills Peninsula died from the disease at Puerto Armuelles in the southwestern end of the Republic of Panama. This indicates that in some manner the wave has crossed the continental divide in southern Costa Rica, and is now threatening to recross the Republic of Panama, but this time on the Pacific side and moving eastward.

This is probably the first time in modern history that a wave of sylvan yellow fever has moved through Panama and Central America in its pure form and with a directional trend due to its canalization in a relatively narrow strip of land by two oceans. It developed its initial focus (November–December 1948) east of the Panama Canal, on the Pacific side of the continental divide. It then moved over the divide at a low point (600–700 feet) into the Chagres watershed (August–September 1949), crossing the Panama Canal and reaching the rain forest on the Atlantic by January 1950. Thence it ran westward to Almirante and the Costa Rican border, remaining entirely on the Atlantic side. The Atlantic watershed of east-central and northeastern Costa Rica were involved from July to October 1951. A seeding of the Pacific side of Costa Rica threatens to involve the Pacific watershed of Panama with an offshoot of the wave.

All of the proved human fatalities so far have acquired their infections at elevations below the 2,000-foot contour, and most of them have occurred definitely below the 1,000-foot contour. This implies that the continental divide can act as a barrier and also canalize the movement of the wave, as it did in Panama in 1949–51. Circumstances which might be conducive to the crossing of the divide are not well understood, for although the Cordillera in Costa Rica is higher than it is in Panama, a crossing has already actually occurred there.

Outbreaks in Nicaragua may not be encountered until April or even July or August in 1952. This is only an inference based on experience in Panama and Costa Rica, and may or may not be applicable to the pertinent climatic, seasonal, and terrain factors of Nicaragua. Probabilities suggest that the wave will keep on moving. As the lowlands and extensive valleys of eastern Nicaragua are involved, new enzootic foci may become established. Whether or not the Pacific watershed north of Costa Rica will be involved remains to be seen, for the divide is broken by Lake Nicaragua at the Costa Rican border.

If the disease does establish itself in Nicaragua this year, and if there are enough critically located population centers involved, the opportunity for a long-term study of the behavior of such a wave will be assured. This

would call for cooperative effort by scientific personnel in all fields of biology, public health, and medicine. On the other hand, the wave may lose itself in uninhabited regions and reveal its presence only sporadically in scattered localities at long intervals, thus not exciting public interest again until a large community is involved. Or it may vanish as did the second Brazilian wave of 1944-45. At its present velocity it may not reach Guatemala and Mexico for 5 or 6 years, but it will continue to constitute a cause of illness and death for the farming settlements in its pathway.

Vineyard Haven Hospital Closed

A decline to about 40 percent of capacity has led to the recommended closing of the Vineyard Haven Hospital of the Public Health Service. The 30-bed facility on Martha's Vineyard, Mass., no longer admits patients and is to be closed as soon as provision can be made for the patients now in the hospital. Its principal beneficiaries are Coast Guardsmen and seamen for whom the Public Health Service will continue full responsibility, transferring all those requiring further hospitalization to the 300-bed Public Health Service Hospital in Boston.

The recent decision to close the hospital was based on the report of a special survey board that only 29 percent of the patients admitted in recent periods were local residents and that comparable Federal facilities were available nearby.

What's in the Health Council Idea?

The thirty-second annual meeting of the National Health Council was held in New York City on March 13 and 14. The program included two symposiums around the general theme, "What's in the health council idea?" One discussion dealt with "citizen participation in community health planning through community health councils" and was chaired by Miss Margaret A. Hickey, a vice president of

the National Health Council and public affairs editor of the *Ladies Home Journal*. The second panel, chaired by Dr. Robin C. Buerki, president-elect of the National Health Council and executive director of the Henry Ford Hospital in Detroit, discussed "health planning and action on the State level through State health councils." *Public Health Reports* presents, in brief, the nine "case reports" discussed.

Citizen Participation in Community Health Planning

Four Case Reports

The Professional Society

It was just about 12 years ago that the Columbus (Ohio) Academy of Medicine began to work with our Council of Social Agencies toward establishment of an organized plan for improving health services.

The first big step was employment by the council of Dr. Ira V. Hiscock of Yale University, to make a survey of health services in Columbus and Franklin County. The survey was completed in 1942. With great satisfaction we can report that nearly all the recommendations of that survey are today actual accomplishments.

Formation of Health Council

One of the first recommendations put into effect was the formation of the Metropolitan Health Council, in 1943. The membership of the council includes eight members appointed by our Council of Social Agencies, eight members appointed by our Academy of Medicine, and seven

members representing the Columbus Dental Society, the twelfth district of the Ohio State Nurses Association, the Columbus Board of Health, the Columbus Hospital Federation, the Colleges of Medicine and Dentistry at Ohio State University, and the Central Ohio Academy of Pharmacy. We believe that this membership constitutes a truly representative group of persons interested in our community health services.

The health council has been made an integral unit of the Council of Social Agencies and also works closely with the Columbus Academy of Medicine. In many cases, chairmen of academy committees are also chairmen of the health council committees.

It is obvious that with this type of organization the health council can

enlist powerful community support to back its studies and recommendations.

City Health Department

The present mayor of Columbus, when he first took office in 1944, called on the newly organized health council for advice about the city health department. Since then, he and the Columbus City Council have followed the report made by the health council almost to the letter.

Services added by the health department as a result of this report include a children's dental health service, seven well-child conferences, daily operation of the venereal disease clinic, annual examination of food handlers and barbers, a restaurant inspection program, a pest control department, and food handlers classes. In addition the meat inspection, milk inspection, and nursing services were extensively expanded. To house these new and expanded services, a \$1,200,000 city health center is being erected.

A survey of needs in the field of mental health by the health coun-

By Russell G. Means, M.D., past president, Columbus Academy of Medicine, and first president of the Metropolitan Health Council, Columbus, Ohio.

ell resulted in the establishment of a children's mental health center. This project was accomplished with aid from such organizations as the Junior League, Community Chest, Children's Hospital, and Ohio State College of Medicine, and is an especially good example of the marshaling of all resources available to get a needed program started as soon as possible.

Other Accomplishments

The health council has also played an important role in initiating hospital building programs. A hospital survey conducted under the auspices of the health council resulted in a $6\frac{1}{2}$ million dollar fundraising campaign. With these funds, two of our general hospitals have already completed expansion and other hospital building programs are under way. We expect to have about 1,200 more beds as a result of these efforts.

Another activity of the health council was a survey of childhood accidents, followed by a workshop to acquaint the community with the extent of the problem and steps which might be taken to reduce the number of such accidents. Institutes and courses in community health programs for the orientation of student nurses, medical students, and staff and board members of voluntary health agencies also constituted an important part of the program.

It becomes apparent that our health council has accomplished much in a comparatively short time. And all the accomplishments have not been listed, by any means, in this short summary.

We would not want to give the idea, however, that all our goals have been reached. For example, we are working toward effecting a merger of the five separate health departments now functioning in our county, and toward an expanded school health program.

Such improvements in health services take time, but we are convinced that the health council idea speeds the achievement of such improvements. When citizens work together—and citizens include the medical profession—in the right

kind of organization—and this means the health council—you can be certain of one thing: Real improvements in health services will begin to appear in short order. We have proved it in Columbus.

The Civic Organization

There are three principal ways in which the civic organization through its members can assist in planning and developing the community health center program. These have to do with the organization, the operation, and the maintenance of the health center.

Organizing the Program

First, the civic organization can be instrumental in helping to create community consciousness of the health problem. The average member of a civic organization is just an average person, and as such he looks at the community health problem much as he does his own health problem, with a philosophy that says "as long as nothing has happened nothing is likely to happen." Therefore, it is necessary to get Mr. and Mrs. Average Member to realize that the problem of community health is his or her individual problem.

In my limited experience in working out a health program in the Mississippi Delta section of southeast Missouri, I have found that citizen participation is best obtained by presenting the problem (and the problem only) to the civic organization and then leading the group into a discussion of ways and means of solution. There follows a logical and natural sequence of individual thought, vocal expression of recognition of individual responsibility, and finally the pledging of time, effort, and often material assistance. If no health committee

exists, one should by all means be created within the civic organization.

The civic organization must never be approached with the thought that a health program is to be sold to them. They must rather be led to realize that as a part of the community it is their program and responsibility, and, therefore, they must actively engage in planning and developing the health program, center, or council.

Following Through

Second, the civic organization has an important part in bringing the health program into being. Under Missouri law, health programs are operated on a single-county basis or through a consolidation of two or more counties. They are supported by a county mill tax, which funds can be used for no other purpose. To set up a health center and work out a health program under this law, three steps must be taken—and here is where the civic organization through its individual membership plays its most important and essential role.

1. A petition for an election to vote the mill tax must be obtained, carrying a minimum of 10 percent of the voters at the last gubernatorial election. Without the help of civic organizations this would be an endless and insurmountable task, for the public today is tax conscious and the individual reaction when such a petition is presented tends to be negative.

2. The petition must be presented to the county court, for its approval and action in calling the election. The committee waiting on the court is made up of members from many civic organizations.

3. In the 90-day interim between court approval and election day, the health committees of the civic organizations and their individual members have the responsibility of carrying the plan and program into each and every voting precinct and on election day the task of getting out the vote.

In my home county, when the county court objected to the expense of judges and clerks for a special election, the civic organizations were

By Edward L. Corbin, past executive secretary, Missouri and Texas Farm Bureau Federations, and president, Board of Trustees, Scott County Health Center and Council.

able to obtain a full quota of clerks and judges who served without pay—a total of over 150 people. The proposition for a mill tax health center was carried by a majority of 8 to 1.

Finally, after the health center is established, its personnel employed, and the program under way, the civic organizations must continue their collaboration through their health committees and members. For example, cooperation with the schools in the conducting of immunization programs and special clinics is best obtained when the Parent Teachers Association uses its influence.

Sanitation Problem

Recently my home town, population 12,000, was confronted with a sanitary sewer problem. The county sanitarian from our health center refused to permit any new homes or industrial development to be tied onto the antiquated and inadequate sewerage system. This necessitated an election to vote a bonded indebtedness of over a million dollars, plus substantially increased taxes to retire it. Of course, this chain of events put the county sanitarian and the health program on the spot, but the civic organizations, namely, the chamber of commerce, women's clubs, federated clubs, and five luncheon clubs, went into action, and a comfortable margin above the required two-thirds majority was obtained in the election.

To summarize briefly: The leadership in the health program that fails to capitalize on the civic organization falls tragically short of opportunity.

The Official Agency

The Washington County (Maryland) Public Health Association is both a health council and a health administering agency, with a unique record of community participation

By William M. Brish, superintendent of schools of Washington County, Md., and active member of the Washington County Public Health Association.

The Growth of The Health Council Idea

Health planning in the United States—for generations the exclusive province of the health officer, the physician, the welfare worker, and other professionals—is becoming a community activity in which the layman is now taking a leading part, according to a preliminary report issued by the National Health Council during its thirty-second annual meeting. The report summarizes the findings of a 2-year nation-wide study of local and State health councils.

At the time the study was begun there were 1,190 local and 34 State councils, three-fourths of which, it appeared, had been formed since 1940 and more than half since World War II. It is estimated that there are today probably more than 1,300 local councils and that State councils are being formed in three additional States.

Local councils, the report showed, are now in operation in one out of four counties in the United States. In each of the 91 predominantly urban counties—those with 50,000 or more population—there is at least one health council functioning.

On most of the health councils, four different types of organizations and agencies are represented: professional societies, official agencies, voluntary health organizations, and civic groups—with civic groups the most numerous. The councils, both State and local, thus bring together the housewife, the physician, the dentist, the nurse, the farmer, the worker, the business man, the educator, the health officer, the public official, the parent, and others with a direct or an indirect interest in community health.

A study of the activities of 276 local councils from 1947 to 1950 showed more than 1,000 specific projects undertaken. The projects ranged all the way from

starting a county health department and promoting hot lunches in schools to establishing clinics and helping local voluntary health agencies initiate programs. They were aimed at problems in such fields as social hygiene, safety, nutrition, industrial health, rehabilitation, maternal and child health, mental care, alcoholism, public health nursing, health education, and sanitation.

The 34 State health councils, the report indicates, were formed primarily to determine state-wide health needs, to promote legislation, to arouse public support for proposed health programs, and to encourage joint planning among health organizations for eliminating gaps and overlapping in their current programs.

Commenting on the report, Dr. Thomas D. Dublin, executive director of the National Health Council, said: "The rapid sweep of community organization for health is one of the most hopeful elements of our postwar society. Everywhere local citizens groups, voluntary health organizations, professional societies, and official agencies are learning to work together to safeguard and improve their community's health.

"The health council is the natural mechanism for such co-operative effort. It brings together all the varying points of view of groups dedicated to the solving of health problems. It is a forum for exchange of opinion, for joint planning and action. And it is the ideal mobilizer of the all-round public support so necessary for community effort."

The National Health Council is an association of 42 voluntary health and welfare organizations, professional societies, official agencies, and citizens groups interested in health. Part of its program is the encouragement of the health council movement.

In local health services. It traces its history to 1915, when the county tuberculosis association was organized, and its name to 1916, when it was known as the Washington County Tuberculosis and Health Association. In 1948, it became the Washington County Public Health Association.

All local official funds for health, except contributions to the State toward the health officer's salary, are disbursed through the association. By pooling official and nonofficial funds, our public health program has become quite flexible. Salary supplements were made when it was desirable to fill health department positions where the official salary failed to attract such qualified personnel as a pediatric consultant, a medical-social consultant, and a supervising nurse; and in another instance, to support a speech diagnostic clinic for a period of 6 months until official funds could continue the service.

The association holds regular monthly meetings to discuss planning, organization, budget, and general problems relating to the county program. It is composed of a variety of groups representing donors of funds and services and recipients of services. Three volunteer health agencies—the Washington County Tuberculosis Association, and the county chapters of the American Cancer Society and the National Foundation for Infantile Paralysis—contribute to the salary and expenses of the executive secretary, appointed in 1950 to administer the activities of these three participants. The association also functions as the county school health council, and it administers the county program of indigent medical care.

In addition, the present membership of the Washington County Public Health Association represents the following agencies or groups: county hospital; county medical and dental societies; Red Cross; county ministerial association; PTA; county commissioners, and mayor and city council of Hagerstown, Md.; business groups such as the chamber of commerce and local manufacturers; and a lay group organized to assist public health nurses.

Contributions of Members

The county hospital's contribution is an important one. A private agency, it owns the building housing the health department. From there, each serves the other: the hospital staff assists in the clinics; health department emergencies are referred to the hospital; there is an interchange of records; and the hospital furnishes meeting rooms for health department personnel and staff meetings. Planning for closer coordination is even now under way, and in fields where there is a mutual community interest, the health department and the hospital collaborate. Some of these fields are laboratory, X-ray, library, visiting nursing, and clinics.

The Red Cross provides eyeglasses for those unable to purchase them. It has helped staff the clinics with its volunteer workers. Besides furnishing transportation to and from clinics, hospitals, and the medical center for special diagnostic and treatment service, the local chapter maintains for use by public health nurses a loan closet well-stocked with layettes, blankets, and sweaters. In addition to promoting a clean-up drive and programs for rodent control and housing, the chamber of commerce sponsored a mass X-ray survey which was partly financed by the tuberculosis association. The official agencies—City of Hagerstown, county commissioners, and the school board—have made cash donations and assisted in planning and administration.

The Washington County Ministerial Association assists in public health education. The PTA helps in planning school health demonstration programs and in establishing good relations between schools and health departments. Like the Red Cross, an organized lay group, whose president is a member of the Washington County Public Health Association, furnishes transportation and volunteer service for the clinics.

Part of the salary of a physiotherapist on the health department staff is furnished by the Washington County chapter of the National Foundation for Infantile Paralysis. The tuberculosis association pays the

fees of a clinician, an X-ray technician, and a clerk at the chest diagnostic clinics. The cancer society supports a cancer detection clinic, gives special services to cancer patients, and furnishes surgical dressings. Some services of physicians and dentists are given without charge and others at an entirely inadequate clinic fee.

As a result of this interchange of material things and services, the community has benefited by excellent public health relations—between the schools and the health departments, between the professional societies and the health departments; between the welfare program and the public health program; and between city administration and county administration. Most important, however, is the opportunity for all the interested agencies to plan together an over-all health program for the community. As a result, each group sees the total program and not just its specialized interests.

The Voluntary Agency

 Citizen participation figured prominently in the formation of our local Mental Hygiene Society and Child Guidance Center. Responses to a questionnaire sent out in 1946 by a special committee of the Springfield Council of Social Agencies showed the public to be keenly interested in such a project. A board, which became the planning body and nucleus of the present Mental Hygiene Society, was therefore formed.

The function of the society is twofold: (1) to administer a mental health clinic, and (2) to conduct an educational program for prevention of mental illness.

Mental Health Clinic

The first job was to set up the clinic. After 2 years, we secured staff, funds, and a location. When

By Mrs. Lydia Dobbins, president, Mental Hygiene Society of Springfield (Illinois).

I tell you that funds, of a sort, came from the County Board of Supervisors, the local school board, and the Community Chest, you may know that considerable citizen effort was expended. We later qualified for Federal money.

An open house announced our existence. Welcoming committees made up of State and local public health officials, prominent doctors, nurses, PTA presidents, and school officials were on hand to explain our role in the community. About 250 citizens attended and many of them became members of the society.

We were fortunate in securing as executive secretary of the society a psychiatric social worker of wide experience who administered the clinic sympathetically and set high standards for the committees. Good leadership is necessary if full citizen participation is to be secured.

School Programs

For 3 years we focused our attention on the PTA, a ready-made, highly motivated group. By the end of the first year, we had a mental health chairman in each of our 30 school PTAs; had given at least one program on mental health in 25 schools; had conducted study classes with parents in four schools; and

had set up a series of lively panel discussions between parents and children in one of our three high schools. At the end of the school year, we culminated this work with an institute for parents and teachers, securing a psychologist from the University of Chicago as lecturer and discussion leader on the topic, "What should a child expect from his parents?"

The psychologist also met with the leading school people of the city and interested them in the study group project idea. Consequently, for the past 2 years, 11 study classes of mothers, some fathers, and teachers have been held. I am sure this child growth and development study project has given "Ma" and "Pa" a better understanding of what makes Johnny tick, as well as bridging the gulf between the home and the school. The Mental Hygiene Society has furnished leaders and moral support for this venture.

We feel that certain recent improvements in school procedure have a definite relationship to this new interest in wanting to understand Johnny. This year, report cards in the elementary schools have been replaced by teacher-parent interviews and chart evaluations of progress and personality development.

High school counselors now visit the home of every freshman. Truancy and the causes for leaving school are being studied.

Another point of contact we have labored with has been the county court. Our testing and psychiatric services are available for every child who comes within its jurisdiction as a dependent or delinquent. Also, as a result of the insistent recommendations of the Mental Hygiene Society, a psychiatrist now sits on the Sangamon County Commitment Board.

National Mental Health Week

Perhaps our most concentrated effort to recruit citizen participation occurs each May, during National Mental Health Week. For the past 2 years we have sponsored a 1-day institute designed to create a wide general interest in problems of emotional maladjustment as they are related to the anxieties of childhood.

For this coming May, we are trying a different approach—seminars instead of institutes. By invitation, three small select study groups are being formed: one, of religious leaders (Sunday-school teachers); one, of employers and personnel men from industry; the third, parents. A psychologist, experienced in each field, will guide them.

Planning and Action Through State Health Councils

Five Case Reports

Virginia Council on Health

For a number of years prior to 1946, a self-appointed, widely representative committee on rural health made studies and published and circulated reports until people were considerably aroused because health services in the smaller communities were

gradually disappearing, with few replacements in prospect. Although medicine at the crossroads had been decreasing for years, many of the factors behind this trend were not generally recognized. That the number of doctors and hospital beds and the amount of hospital insurance had to be increased was agreed. Something akin to a ground swell was under way; more and better health services had to be provided.

Encouraged by the Virginia Tuberculosis Association, H. B. Mulholland, M.D., then president of the Medical Society of Virginia and a leader in State and national efforts for better rural health services,

called together in Richmond a representative group of agencies directly or indirectly concerned with health services.

Organization

This was in 1946, and that year the Virginia Council on Health and Medical Care was organized with 37 members, now grown to 52 statewide organizations and about 100 local units. The council is simply organized. Its constituent membership includes the State health department, Virginia Cancer Society, the Virginia Tuberculosis Association, the Office of the Commissioner of Mental Hygiene and Hospitals—

By William T. Sanger, Ph.D., chairman, Virginia Council on Health and Medical Care, and president, Medical College of Virginia.

organizations devoted solely to health—as well as organizations having certain health interests, like the Virginia Federation of Home Demonstration Clubs and service clubs. Local councils and other organizations have been found to be effective in carrying out projects in their communities.

A well-set-up health council affords its membership opportunities to learn the programs, interests, and problems of its member organizations. This is a recurring need and can be accomplished both by brief reports at meetings and by material circulated from headquarters or from council members directly.

Major Accomplishments

First, the council tackled a comprehensive legislative program, its effectiveness depending upon the education of the public. Bulletins were circulated by thousands. Many community meetings were addressed by selected speakers, and interested organizations worked through their memberships. For example, the Hill-Burton hospital construction program was given tremendous impetus and large State financial support in addition to that provided by the Federal Government and local communities. We are sure this would have been impossible otherwise. Furthermore, almost every other health interest has benefited by our legislative emphasis. The issuance of public opinion reports is now routine. The council assigns special tasks to constituent members. These tasks may call for legislative and educational work, or special studies.

One important council-directed study was a survey of the need for health service personnel. The study revealed that 33 counties (one-third of the State) lacked physicians and other health workers. A further task is to study these counties on a community basis to ascertain the cause of health service shortages, whether economic, social, educational, or religious. An earlier study dealt with practically all phases of rural health conditions.

Last fall, we sponsored a state-wide conference on crippled children at the request of the Nemours

Foundation, Wilmington, Del. Many fundamental conclusions were reached at the 2-day program, including a decision to set up a coordinating committee for crippled children's work. That committee has now met and outlined a promising action program. Next fall, the conference on crippled children will be devoted to speech defects and their correction. Also, the Nemours Foundation has allocated \$45,000 for crippled children's work in Virginia with a prospect that such grants will be put on a continuing basis.

Cooperation with the State department of mental hygiene and hospitals and the Virginia Mental Hygiene Society has aroused interest in our mental hygiene clinics and institutions and resulted in substantial appropriations.

Future Programs

Continued emphasis will be given to mental health; to the better distribution of physicians and medical personnel; more hospital beds; special studies on the need and distribution of medical personnel; community health inventories; complete coverage of public health services; enriched and enlarged training opportunities for medical and related personnel; nutrition; crippled children; hospital and health insurance; and placement of physicians within the State.

The accomplishments of the Virginia Council have been next to phenomenal. Its flexible and broadly conceived potential for action fits it for attacking almost any issue with some guarantee of success. Its balance between professional and lay membership is undoubtedly one of its primary strengths.

Ohio Rural Health Council

The Ohio Rural Health Council originated in 1941, with the appointment of a committee to study the need for more adequate health services and facilities for rural areas. The member-

By Mrs. Arthur McCoy, vice president, Ohio Rural Health Council.

ship is now comprised of representatives from 22 state-wide organizations interested in the problem—including four State government departments, the Ohio State Medical Association, the Ohio Farm Bureau Federation, the State Grange, the Farmers' Home Administration, and the Agricultural Extension Service of the Ohio State University—and an equal number of area members, each representing four counties.

Five-Point Health Program

To acquaint the rural people with the health opportunities already available and to encourage expansion of rural public health activities, the council gradually developed the following five-point program:

1. Assembling and disseminating information to inform rural people of the health programs in operation.
2. Encouraging organizations and agencies to initiate programs of health education within their own organizations.
3. Holding State and district meetings to afford opportunities for lay and professional people to discuss health problems together.
4. Training leaders in rural areas to assume responsibilities in the promotion of health activities.
5. Encouraging counties to make surveys and studies to determine local health problems and needs.

Carrying Out Our Program

How are we succeeding in accomplishing these aims? In 1947, at the request of the cooperating agencies, the Agricultural Extension Service accepted the responsibility of employing and supervising an extension health specialist. State conferences have been held annually since 1944; a district conference held in 1947 proved so successful that two were held the following year, four in 1949, four in 1950, and eight last year. We are working toward the goal of annual meetings in each of the 22 districts.

As a result of the growing interest in better public health, the number of full-time health departments in the State is increasing and programs are being enlarged. Fifteen counties have organized active, voluntary

councils, which are enthusiastically working for better health programs and organizations. Two counties have conducted exhaustive surveys to determine local health conditions and have launched enlarged health programs.

Several of our cooperating organizations have set up special programs in the interest of better rural health. The Ohio State Medical Association, for example, now has a rural health committee—with a full-time worker—serving as a policy forming group within the organization and has initiated a system of scholarships to encourage rural medical practice. The Ohio Farm Bureau is promoting a program of health education among its members. The Ohio State Grange requires a minimum of two health programs yearly for its 800 subordinate granges. The Ohio Veterinary Medical Association, in cooperation with the Ohio Departments of Health and Agriculture, has prepared and distributed folders concerning animal diseases affecting man.

Although we feel that the Ohio Rural Health Council has made real progress during its short existence, we realize that we have only begun to prove what may be accomplished when organizations and agencies

work together toward a common goal. The opportunity to get together frequently, on both State and local levels, to consider health problems and to evolve methods whereby all may work together, harmoniously and understandingly, is the key to true coordination of rural and professional groups. We of the Ohio Rural Health Council feel that we face great opportunities, and at the same time—through our growing knowledge of these problems—great responsibilities.

Pennsylvania Health Council

PHR If there is need for improved health in a community, state, or nation, there is need for a health council at that level. Everyone must admit there is always need to improve health, and I believe there is always need for a health council.

In initiating new health projects, health departments, medical, dental,

By Gilson Colby Engel, M.D., president, Pennsylvania Health Council, and professor of clinical surgery, Graduate School of Medicine, University of Pennsylvania.

and nursing societies, and voluntary health groups are usually their promoters. Obtaining public acceptance and support can be an important function of a health council. Through its diversified membership it can coordinate ideas, and through its wide public contacts it becomes a powerful factor in the education of the public and the legislators.

How We Grew

In Pennsylvania, the State medical society requested the governor to have a health survey made by the American Public Health Association. The survey report revealed many points calling for changes, some involving new legislation. It indicated the need for a health council. At the time, 1949, I was president of the State medical society, and I requested our committee on rural health to invite organizations to meet and discuss the possibility of forming a State health council. Delegates from 40 professional, Government, lay, and consumer groups interested in health attended and unanimously voted to organize the Pennsylvania Health Council.

A meeting for permanent organization was called for February 11, 1950, in Harrisburg. Thirty organizations were represented. Bylaws were unanimously adopted. The officers—president, two vice presidents, secretary, treasurer, and five members-at-large to the executive committee—were elected. Annual membership dues were set at \$25 for each organization.

Among the present membership totaling 43 organizations are: Association of the Junior Leagues of America (Region III); Pennsylvania Bureau of Rehabilitation; Hospital Association of Pennsylvania; League of Women Voters of Pennsylvania; Pennsylvania Association for the Blind; and Pennsylvania League for Planned Parenthood.

Between annual meetings the health council functions through a 14-member executive committee composed of its five officers, five elected members-at-large, and four committee chairmen. The committee meets bimonthly in Harrisburg to conduct the council's business.

The story of health councils throughout the United States is told graphically in this exhibit, shown at the National Health Council meeting in New York. The exhibit was shown originally at the 1951 meeting of the American Public Health Association in San Francisco, where this picture was taken.

What We've Achieved

Financing is a difficult problem. The \$25 dues, amounting to about \$1,000 annually, do not go far, but we feel we have accomplished a great deal on that annual income.

What has our infant organization accomplished in our short existence? What are we doing now?

1. We started a campaign which became a vigorous fight over neglect of the tuberculosis situation, with wide repercussions.

2. The council, through its president, was invited to confer with the governor-elect concerning a new Commonwealth secretary of health and to sit on a nominating committee for the new candidate. The recommendation was followed.

3. We cooperated with the law schools at Pittsburg and Pennsylvania Universities in the drafting of health legislation creating a merit system and local public health units. We backed this legislation and urged our member organizations to campaign for its passage with the result that the bills became law on August 24, 1951.

4. We have backed new narcotic legislation which created more severe penalties for the dispenser.

5. We support the new secretary of health in the carrying out of the new laws and in the appointment of new trained health personnel.

6. We support drives of our member organizations.

7. We are stimulating interest in a health education program for employees of the health department.

Missouri State Health Council

 The motivation for the creation of a Missouri State Health Council came from a number of sources. The primary force was a realization on the part of several of the official and nonofficial agencies that there existed no mechanism for easy discussion of the programs and policies

of the organizations. It was decided that the Committee on Rural Medical Service of the Missouri State Medical Association should take public leadership, with the immediate backing of the Missouri Farm Bureau and the Missouri Tuberculosis Association, in sponsoring a conference to discuss the problem. The conference resulted in the establishment of a state-wide health council which would "bring together state-wide organizations and agencies with a fundamental interest in health for discussion, planning, debate, and interchange of opinions; to serve as a clearinghouse on health problems and programs; to facilitate joint planning in order to encourage coordination and effort on State and local levels."

Objectives of the Council

The health council determined three main objectives: (1) self-education of its membership as to the program and policies of its constituents; (2) furtherance of local health councils, whose primary purpose was to survey their areas for a determination of health needs; and (3) furtherance of county health units under either one of two enabling acts.

Under the leadership of the bureau of health education of the division of health, the Missouri Farm Bureau, and the Missouri Tuberculosis Association, some 50 county health councils have been established, and 15 new county health units brought into existence.

The Missouri State Health Council is not an action group but rather a discussion group. It is financed by \$10 annual dues from state-wide member organizations. The community health councils, as associate members, do not contribute to its support. Since there is no salaried staff, the State council works principally through its member organizations and their staffs.

The State council has acted as a citizens committee for an American Public Health Association survey of the State division of health, and has sponsored annual public meetings, which have been attended by as many as four and five hundred peo-

ple. Council meetings are held quarterly, and meetings of the executive committee, more frequently.

Currently the council is engaged in the first coordinated state-wide investigation of the problem of the hospitalization of the indigent ill. It is also preparing materials for assisting local councils.

Michigan Health Council

The Michigan Health Council is organized along the lines of the National Health Council, with a membership of 26 state-wide organizations. It spends about \$20,000 a year.

Our major field of activity is in assisting community health councils. We believe that the health problems of Michigan and of America will not be solved unless they are solved on the local community level. We do not enter any community, however, unless we are invited to do so by a local group. We have discovered by experience that community organization can be assisted and nurtured by state-level stimulation, but the desire for better health and the will to take necessary steps to achieve it must reside in the community. We assist the local health councils by helping them to organize, advising them on long-term and short-term objectives, conducting State and regional meetings for exchange of information, and publishing a monthly bulletin for the same purpose.

Local Aid

Although each community health council determines its own objectives, we try to advise against attempting too much the first year. A combination of a short-range objective, which can be reached in a year, and a long-range objective, which will provide continuing reason for existence, seems to constitute the best formula for our community health councils.

By Donald E. Pratt, chairman, Missouri Health Council, and executive secretary, Missouri Tuberculosis Association.

By John S. DeTar, M.D., president, Michigan Health Council, and past president, Washtenaw County Medical Society.

Some of our community health councils (we have 32 organized now) are old; some are new. Both the long-range objectives and the current projects of these community health councils vary in accordance with local needs. This divergence in activities stands out as a conclusive argument for the need of action on the community level, as contrasted with determination of need from a centralized national headquarters.

Some of the projects of these community health councils are:

1. Self-survey on health of an entire county of 46,000 rural people to determine objectives for county health council.
2. Immunization program.
3. Campaign for enrollment in prepaid hospitalization and medical insurance program.
4. Weekly health column in newspapers.

5. Regional conference of community health councils for exchange of information.

6. Formation of a blood bank (rural).

7. Educational programs in small towns.

8. Topical fluoride dental program among school children.

9. Formation of county health department.

State-Wide Projects

The Michigan Health Council presents awards each year to outstanding community health councils, and to newspapers and magazines for meritorious work in the health field.

We hold an annual rural health conference in Michigan—with 94 co-sponsors. We publish annually a directory of all Michigan health organizations.

We have made a film depicting the steps in organizing a community health council, which will be avail-

able for other State health councils for use in their States. We also operate a film information service for assistance of community councils.

Our members are working on the development of a "periodic health appraisal" to replace the annual examination for cancer, heart, diabetes, tuberculosis, and other diseases. This is a type of cooperative effort possible on the State level.

We plan to hire a full-time field secretary to work with the community councils, and a full-time man to work exclusively with high school students in assisting them in choosing a career—with the attempt to guide them into the fields of medicine and associated activities, which so sorely need them.

Our only handicap is lack of money.

We believe a State health council fills a need which no one other organization can quite fill.

New Chief of Division of Commissioned Officers

Dr. Erwin C. Drescher has been appointed chief of the Public Health Service's Division of Commissioned Officers. He succeeds Dr. Eugene A. Gillis, who has been assigned as consultant to the Lebanese Government. During his 17-year career in the Regular Corps of the Public Health Service, Dr. Drescher has served as deputy State health officer of Oregon, director of venereal disease control and assistant State epidemiologist in Kentucky, and chief of medical services in Public Health Service District No. 1. Before coming to Washington in 1951 as operations officer of the Division of Commissioned Officers, he was Public Health Service consultant to the City of Pittsburgh.

Dr. Drescher is a graduate of the University of Michigan and of the University of Michigan School of Medicine and holds the degree of master of public health from The Johns Hopkins University.

Unstained Slides for the Diagnosis of Certain Treponematoses

By WALDEMAR E. COUTTS, M.D.,
EDNA SILVA-INZUNA, and
GUILLERMO MORALES-SILVA

The procedure and techniques we describe may be helpful in diagnosing treponemal or spirochetoidal infections in localities where a microscope is not available or, if available, lacks a condenser for dark-ground illumination.

Before communicating our results, we examined slides from *Treponema pallidum* lesions sent to us from different regions of our territory, which extends from parallels 18 to 56, and others coming from different countries and containing material from open lesions produced by other treponemata than *pallida*.

Slides to be sent to the laboratory can be dried at room temperature without previous fixing with any substance; they may be fixed with ether-alcohol or, preferably, a 10-percent formalin solution. A slide or a piece of window glass containing a thick coating of dried material can be sent by ordinary mail or by air mail, wrapped in common or filter paper. After this material is received in the laboratory it is mixed with tepid normosalt on the same slide or glass; thin films are laid on unscratched glass, fixed with 10-percent formol, rinsed in tap water, and dried over a low flame.

Dark-ground observation of the slide can be made with a powerful lens or under double immersion. Under dark-ground illumination, spiral micro-organisms appear as brilliant as when seen in fresh material, only they are motionless. Epithelial cells, leukocytes, and red blood corpuscles also preserve their shape and

characteristics. The bodies of treponemata appear as a succession of brilliant dots, varying in number from 4 to 16 or more, sometimes linear, at other times slightly curved in appearance. Spirochetoidea, on the contrary, show their bodies as a continuous, flexuous, worm-like unit, tapering towards its extremities. Curves are more open and fewer in number.

Dark-ground illumination of fixed unstained slides for the diagnosis of certain treponematoses. A sample of what can be obtained with a 6L (Leitz) lens and a No. 10 (Zeiss) photo-ocular lens.

Fuchsin-stained preparations of material containing treponemata or spirochetoidea can also be observed under dark-ground illumination; spirochetoidea appear brilliant and colored, treponemata appear brilliant, slightly colored, or, more commonly, unstained.

ACKNOWLEDGMENTS

The authors wish to acknowledge the kindness of the Pan American Sanitary Bureau (WHO for the Americas) and especially of its Director, Dr. Fred L. Soper, and that of Lieutenant (SS) Gérard Boyer, of Haiti, in making available slides containing yaws material.

Dr. Coutts and co-authors are with the Department of Social Hygiene, Chile Public Health Service.

Shattuck, Chadwick, and the Engineer In Public Health

By GORDON M. FAIR, Dr.Ing.

In the now remote spring of 1850, there fell from the hands of the State printer of the Commonwealth of Massachusetts in North America a "Report of a General Plan for the Promotion of Public and Personal Health." The recommendations contained in this report were eventually to become the charter of public health in America. Among them were recommendations that set the example for the participation of engineers in developing the public health policy of the country.

The principal author of this report was Lemuel Shattuck, a Boston bookseller, teacher, and public servant, who had written its more than 500 pages in slightly less than a year. This he had done, furthermore, with the expenditure of but \$500. However, Shattuck could never have accomplished this task had he not been able to "drink deeply from the Pierian spring" that welled through the writings and reports of Sir Edwin Chadwick. Sir Edwin he acknowledged to be "the individual to whom, perhaps more than any other, the cause [of sanitary welfare and improvement of the people] was indebted" (1).

The substance of Shattuck's document was contained in 50 recommendations, 36 of which,

according to an analysis by Winslow (2) in 1949, are now "universally accepted practice"; but 4 are "unimportant or, in some degree, unsound"; and 10 although "as sound as the 36 proposals that have been generally accepted" were sufficiently advanced in their objectives that "their importance has as yet not been fully recognized."

The Need for Engineers

Among the half-hundred measures that Shattuck proposed was the creation of a general board of health composed, so far as practicable, "of two physicians, one counselor-at-law, one chemist or natural philosopher, one civil engineer, and two persons of other professions or occupations; all properly qualified by their talents, their education, their experience, and their wisdom" (1). Two reasons were given why the members of the board should not be selected exclusively from one profession. In the first place, Shattuck anticipated that "numerous questions requiring a knowledge possessed by different professions" would be presented to the board of health "for discussion and decision." Second, the promotion of public health, in Shattuck's mind, was a matter that concerned "every profession and every person." The services of medical men he rightly considered "indispensable, but the services of other professions, and of every person in their respective spheres," he was convinced, "must be put in requisition before reform can [could] be complete." According to Shattuck "the idea which too generally prevails, that

Professor Fair is Abbott and James Lawrence professor of engineering and Gordon McKay professor of sanitary engineering, Harvard University. This paper is based upon material presented in a Chadwick Public Lecture delivered at the Royal Sanitary Institute, London, in June 1950.

everything relating to health belongs exclusively to one profession, operated against sanitary improvement."

The civil engineer member of the board, Shattuck suggested, should possess "competent knowledge to determine the best methods of planning and constructing public works, and the best architectural sanitary arrangements of public buildings, workshops, and private dwelling houses." Possession of such competence, Shattuck was convinced, would make the engineer an exceedingly valuable member of the board, and so he has proved to be.

The enunciation of the principle that engineers should have a part in public health had been anticipated by Sir Edwin Chadwick, who, in 1842, had suggested:

That for the protection of the laboring classes and of the rate payers against inefficiency and waste in all new structural arrangements of the protection of the public health, and to insure public confidence that the expenditure will be beneficial, securities be taken that all new local public works are devised and conducted by responsible officers qualified by the possession of the science and skill of civil engineers (3).

The minds of Chadwick and Shattuck, as the minds of great men so often do, moving in much the same channels, therefore, appear to have assured the early participation of engineers in the public health work of their respective countries, but for each in its own way. In the older civilization of Britain, participation has during this past century of public health progress been confined perhaps more narrowly to the economic design of sanitary works as a peripheral contribution of the engineer to public health. In the more fluid civilization of America, engineering participation has been afforded somewhat wider scope in the formulation of public health policy and in its implementation. In this sense, perhaps, the American engineer has moved closer to the central core of public health, greatly to its ultimate advantage.

The Great Sanitary Awakening

That we may establish a base line for the accomplishments of the last century, let us turn to a few examples of on-the-spot reporting of sanitary conditions in the mid-nineteenth century and adjacent decades.

Lagging behind the renaissance in arts and letters, the scientific renaissance had begun to flower in the eighteenth century. An opportunity had been afforded thereby for its fusion with the spirit of humanitarianism which pervaded the end of the eighteenth and beginning of the nineteenth century in Britain. There resulted the great sanitary awakening that swept over the emergent democracies of the world.

The great sanitary awakening is associated, in particular, with the growth of cities, which was a necessary element of the industrial revolution. Scientific discoveries and engineering inventions had created centralized industries. To these, people flocked for employment. On the whole, this was a good thing. Certainly it advanced the standard of living of vast numbers of men. But absence of restrictive legislation soon led to the exploitation of labor, and absence of community organization created slums. Through these slums the apocalyptic horsemen of pestilence and death often rode their steeds unchecked.

The community facilities of the mushrooming industrial cities were generally overtaxed. In particular, the need for the abundant distribution of safe water, for the effective disposal of human wastes, and for the decent housing of swelling tides of humanity could not be met. The means and knowledge to cope with this new situation were not immediately at hand. Too often water was drawn from polluted rivers or from shallow wells in crowded sections of the community. It was then "distributed in courts by standpipes on intermittent days. The fatigue of fetching it was so great that they (the inhabitants of the courts) only used it for purposes which they deemed of absolute necessity, such as cooking; they rarely bestowed much of it on their clothes or persons" (4).

A single quotation from the report of the Poor Law Commissioners (3) gives a picture of housing conditions and of the need for sanitary sewerage in Britain a hundred years ago.

Many dwellings of the poor are arranged "round narrow courts having no other opening to the main street than a narrow covered passage. In these courts there were several occupants, each of whom has accumulated a heap. In some cases, each of these heaps is piled up separately in the court, with a general

receptacle in the middle for the drainage. In others, a pit is dug in the middle of the court for the general use of all the occupants. In some the whole courts up to the very doors of the houses are covered with filth. Around this mass, the cottages of the residents are arranged, having no back outlet, no back windows, or other means of ventilation. The windows and doors of the houses open and look towards this mass; and all the air supplied to the inmates is obtained through these doors and windows. The residents were very frequently subject to fever, and were always regarded as the first to be affected by any epidemic disease.

To remedy conditions such as these, the discharge of human wastes into existing storm drains was permitted at the beginning of the nineteenth century. The system of combined sewerage was thereby initiated, and the earlier drainage works of most metropolitan communities were subsequently developed in accordance with this scheme. Terminating in nearby water courses, the drains discharged quantities of waste materials that more often than not overtaxed the receiving capacity of these waters. The nuisances that had apparently been so happily removed from dwellings by water carriage were then concentrated along the streams.

Rain to River, Sewage to Soil

First the smaller ones and then the larger water courses began to "seeth and ferment . . . in Augean foulness." As a remedy, many of the smaller streams were, therefore, converted into sewers; but the larger bodies of water had to remain open to view and other sensory disapprobation. I shall spare you a description of the Thames in the hot summers of 1858 and 1859 as recorded by Dr. Budd in his classical treatise on "Typhoid Fever, Its Nature, Mode of Spreading, and Prevention," and shall only recall the rhyme of Samuel Taylor Coleridge about the city of Cologne, which he visited about 1798.

"The river Rhine, It is well known,
Doth wash your city of Cologne;
But tell me nymphs! What power divine
Shall henceforth wash the river Rhine?"

Engineers would have done well to heed as early as 1847 the earnest recommendations of Sir Edwin Chadwick (5) for the introduction of the separate system of drainage whereby the storm flows would have reached the water courses unaffected by the wastes from habita-

tions and industries, while the sanitary flows would have been led away in much smaller conduits to a point where they could be disposed of without nuisance, if need be, after suitable treatment. "The rainfall to the river and the sewage to the soil" was the phrase that epitomized the Chadwick doctrine.

In spite of such admonition and that of Chadwick's great engineering associate, Sir Robert Rawlinson, municipalities continued, on the grounds of expediency and short-range economy, to elaborate their storm-drainage systems into combined sewerage works, greatly to the disadvantage of ultimate amenities in the city plan. Even the capital city of Paris, which did not complete its sewerage until many years later, failed to take advantage of the hygienically and esthetically more desirable separation of sanitary and storm flows. Although Paris did not adopt the separate scheme, Sir Edwin Chadwick may well have promoted the speedier institution of sewerage in that city by his suggestion to Napoleon III in the winter of 1865-66 which is recorded by B. W. Richardson (6) as follows:

Shre, they say that Augustus found Rome a city of brick, and left it a city of marble. If your Majesty, finding Paris fair above, will leave it sweet below, you will more than rival the first Emperor of Rome.

It is evident from these descriptions that the foremost public health needs of the mid-nineteenth century were for adequate and pure water supplies, and for the safe removal of wastes from human habitations. These matters became the responsibility of civil engineers who were experienced in hydraulics. Sir Robert Rawlinson was in his day probably the leading practitioner in this field. But there were many others, particularly in Britain, among whom was John Roe. It was he who accepted Sir Edwin Chadwick's suggestion that vitrified tile pipe be used in sewer lines. In his report to the Harrow local board of health of 1854, Roe said:

The introduction of stoneware pipes for general drainage arose from a suggestion made by Mr. Chadwick to me, in his desire to obtain smooth interior surface; and the first sewer pipes made for that purpose in the metropolis were for the Holborn and Finsbury office.

It is understandable, therefore, that Sir Robert Rawlinson should have dedicated his Lectures,

Reports, Letters, and Papers on Sanitary Questions (1876) "To Edwin Chadwick, Esq., C. B., as the Chief Promoter of Modern Sanitary Works and Appliances."

The Scientific Foundation

Although James Simpson had introduced the principle of sand filtration as early as 1829, in order to purify the waters gathered from the Thames by the Chelsea Water Co., and although Dr. John Snow had demonstrated by 1849 that fecal pollution of drinking water was a major factor in the dissemination of cholera, these were judgments, as it were, *ex pede Herculem*. Public health, and with it public health engineering, had to await the discoveries of Louis Pasteur before the full body of knowledge and the measures of sanitary accomplishment could become available. Thenceforward, the engineering objectives as well as the means for attaining them became clear.

Filtration for the sake of improving the palatability of water was tied to the more important use of filtration for the prevention of enteric disease. Sewerage for the purpose of avoiding nuisance was made ancillary to waste disposal for the safeguarding of water supplies, bathing places, and useful aquatic life. Sewage treatment for the utilization of the fertilizing ingredients of municipal sewage as well as its water value was made subservient to suppression of an ever-growing list of intestinal infections. In the course of time the *Index Expurgatorius* included, among causative agents, not only bacteria but also protozoa, worms of many kinds, and finally viruses.

In America, the need for sanitary reform led to the establishment, in 1886, of an engineering department in the Massachusetts State Board of Health. This department was given the responsibility to protect the purity of inland waters. By allying to itself not only engineers but also chemists and biologists and by meeting its responsibilities in a spirit of research and investigation, this department established itself firmly in public health service.

Today, no State or Territory of the United States is without its public health engineering organization; neither are the United States Public Health Service, the four medical depart-

ments of the Armed Forces and the Veterans Administration, the Atomic Energy Commission, and the Tennessee Valley Authority. Engineers sit on the committees of the National Research Council and are attached to the headquarters staff of the American National Red Cross. Engineers have been directors of the health and sanitation effort of the Institute of Inter-American Affairs, and an American engineer heads the environmental sanitation division of the World Health Organization.

The Chemist and Natural Philosopher

A word should be interpolated here about the chemist or natural philosopher whom Shattuck included in his proposed board of health. This member of the board, according to Shattuck, would have to answer many questions and make special investigations "relating to the influence of the elements on the production or prevention of disease." It is the happy alliance of the chemist, the biologist, and the engineer with the medical profession that has, in large measure, accounted for the progress that has been accomplished in the promotion of the public health by sanitation of the environment. Chemists and biologists have, indeed, had to answer many questions of fundamental scientific importance, and they have had to make many special investigations. Without these, it is only fair to say that the works of the engineer and their management would often have been ill-conceived and inadequate in performance.

The presence of hydraulic engineers in health departments led medical officers of health to seek their advice first of all in matters related to water, such as water supply, sewerage, the sanitation of swimming pools and other bathing places, the control of shellfish-laying areas, and, in certain parts of the country, the control of malaria and other insect-borne diseases in which the insect vectors can be attacked in their aquatic habitat by hydraulic and related operations.

Sanitation of the Environment

In the course of time, the familiarity of public health engineers with the control of en-

vironmental factors that were implicated in the spread of disease made them available to assist in the solution of numerous additional problems. Among them are the following: (a) the sanitation of the air both in and out of doors, in habitations and workshops, in airplanes and in vehicular tunnels; (b) the sanitation of food, in particular of milk during production, conditioning, storage, preparation, and distribution; (c) the disposal of solid municipal wastes, especially food wastes; (d) the control of animal and insect vectors of disease with special reference to their presence in dwellings and other structures; (e) the control of noise; and (f) the provision of adequate light. Many of these environmental factors are implicated in one way or another in the complex problems of housing, industrial hygiene, school sanitation, and town planning.

Given a high place in the formulation of public health policy and the development of measures for the preservation and promotion of public health, engineers have, however, not only been called upon to advise communities and private organizations and individuals about sanitary measures and needs. They have also been asked to give voice, in the halls of parliaments, to the public health requirements of municipalities and rural areas. They have, within public health bodies, been required to exercise such measure of police power as has been needed to enforce sanitary regulations. They have been instrumental in arousing public interest in sanitary progress. They have been put in charge of researches that have advanced the art and science of sanitation. They have become part of the public health team assigned to the suppression of sudden outbreaks of disease. Finally, they have been mobilized in time of disaster and war to coordinate the management of emergency and military sanitation.

Sanitation of the environment is indeed peculiarly a responsibility of the engineer, because his profession, more than any other, is fitted to direct the use of men, money, and materials to the purpose of securing the prosperity and well-being of mankind. The environment of modern man has, in fact, been created in large measure by the exercise of engineering skills. What has been asked of the engineer,

therefore, in a material sense is that he hold in check, as well as apply, the fire which his protagonist Prometheus wrested from the gods.

Organization for Engineering

The Massachusetts Department of Public Health, which grew out of the recommendations of the Shattuck Report of 1850, stands as a leading example of governmental organization for the protection and promotion of the public health through engineering activities. In 1952, this department was serving a population of about 4.5 millions, including the large metropolitan area of Boston. It is directed by a commissioner of health who has the advice of a public health council and the aid of three deputy commissioners.

The third deputy commissioner is an engineer. He is director of the bureau of environmental sanitation. He is also the chief engineer of the division of sanitary engineering and supervises the division of food and drugs.

The division of sanitary engineering is concerned with water supply and water pollution control, with sanitary works at State institutions, with hydrology and hydrography, with housing and plumbing, with camps and other shelters, with offensive trades and nuisances, with cemeteries and mausoleums, and with shellfish sanitation. The division staff includes 26 engineers, 14 chemists, 2 bacteriologists, 2 biologists, 6 sanitarians, 1 supervisor of public health information, and 28 assistants and clerks. It includes a central analytic laboratory, a district analytic laboratory, and the well-known Lawrence Experiment Station.

The division of food and drugs is directed by a chemist. Its responsibilities include veterinary food inspection, other food inspections, and inspection of bedding and upholstery. Drugs are controlled through the food and drug laboratories. Since the sanitation of food is so much a matter of education of the workers in food industries and of food handlers of all kinds, a coordinator of environmental sanitation cooperates with the division of food and drugs. He is directly responsible to the chief sanitary engineer. His duties extend also to cooperation with the division of occupational hygiene of the Department of Labor and In-

dustries. The division of food and drugs comprises 2 veterinarians, 9 chemists, 2 bacteriologists, 15 food and drug inspectors, and 13 assistants and clerks.

In Massachusetts, the division of occupational hygiene is attached to the department of labor and industries rather than to the department of health. Environmental sanitation being an important part of occupational hygiene, however, there is cooperation between the two departments of State government through the chief sanitary engineer. The division of occupational hygiene is directed by a physician, and includes a laboratory. The personnel of the division includes 1 physician, 2 engineers, 4 chemists, 2 nurses, and 5 assistants and clerks.

The Massachusetts pattern of engineering organization for public health is repeated in many other States and to some degree in the organization of the Public Health Service. In the latter, the chief engineer bears the title of Assistant Surgeon General. This is descriptive of the historical origin of the Public Health Service in the Marine Hospital Service rather than of the functions assigned to the chief engineer, which are engineering in nature.

Accomplishments—Direct and Indirect

Many of the contributions of engineering to public health cannot be measured by statistics of morbidity and mortality, for they are allied more closely to the enhancement of human comfort and well-being than to the direct prevention of disease and death. There is, however, clear evidence of the accomplishments of the engineer in public health in terms of reduced morbidity and mortality.

Historically, for example, the control of the water-borne enteric infections became the first concern of engineers associated with the new public health movement. In Massachusetts, deaths to the number of 1,333 were ascribed to typhoid fever in 1870, when the population of the State was 1.5 millions, and but 13, in 1937, when the population was almost three times as great.

Typhoid fever and diarrhea and enteritis in infants present another primary illustration. In Pittsburgh, prior to 1907, when the Alle-

gheny River water supply for the city was first subjected to filtration, the annual typhoid fever death rate had stayed close to 120 per 100,000 population. Filtration was responsible for a dramatic drop of almost a hundred points. Chlorination subsequently eliminated the water supply as a source of typhoid fever, and pasteurization of the milk supply of the community undoubtedly contributed to the decline in this enteric disease. The principal contribution, however, was in the slow but sure elimination of diarrhea and enteritis as an important cause of death of infants and young children.

Accomplishments in magnitude similar to those cited for the enteric infections could be shown for the reduction of malaria, murine typhus, and silicosis, and for yellow fever and other mosquito-borne diseases, for hookworm disease, for food-borne epidemics, and for numerous industrial hazards.

What of the Future?

The record of the past inevitably invites us to "look upon the seeds of Time and say which grains will grow and which will not." Although engineers do not lay claim to the gift of prophecy, they are, by force of circumstance, called upon to look into the future in order that their works may meet not only contemporary needs but that these works may serve well for many years to come. The normal period of design for some of the great structures that serve the sanitary requirements of communities may well reach a half-century. It is in the forecast of the future that the soundness of engineering judgments is, therefore, often tested.

The population of the world doubled during the nineteenth century under the impact of the industrial revolution, the speeding of communication, the intensification of agriculture, the discovery of new sources of energy, and the improvement in public health. It may well treble or quadruple within our own century. The sanitary competition for the elements of human existence will thereby grow steadily more intense.

Although we have learned how to put the fresh waters of the earth to use for multiple purposes, we shall have to become ever more jealous of them, and husband them more care-

fully both as to quantity and quality. In spite of our great investment in drainage schemes, we must be ready to replan our cities not only for better surface amenities but also for that "sweet below" for which Sir Edwin asked Napoleon III. We shall have to combine the recreational use of water with its sanitary protection. In all of this we must not fail to acknowledge that progress in the control of water-borne diseases imposes upon us ever greater caution, for we are constantly raising the level of nonimmunity of our people.

The lowering of the ground-water table and the encroachment of the sea upon our subsurface waters makes for anxious thought. We must learn to conserve this important source of water. There are many places in the world where we may even have to turn brackish waters into sweet. The progress in ion-exchange methods for this purpose is most encouraging, but the possible use of solar energy for the production of fresh water must not be overlooked. We are learning to become rainmakers, and the greater comprehension of micrometeorology that is needed to this end may help us also to place under our command the movements of the atmosphere above great industrial cities.

Air cleanliness is becoming an ever greater challenge. In areas of great atmospheric stability the growing pollution of the atmosphere is, in fact, reaching frightening proportions. There must be no more Donoras. Neither must great cities be permitted to be blanketed by smog, which shuts out sunlight, deprives us of beneficent radiations, and reduces the standard of attainable cleanliness.

Although we know how to disinfect air, the great mobility and communality of this element makes the control of airborne, droplet-borne, and dust-borne infections very difficult. Were it not for the chemotherapeutic agents and antibiotics, our record of respiratory infections would be far less satisfying than it is.

Marvels have been accomplished in the preservation of food, in its sanitary production, storage, transportation, and distribution. Yet

the number of food-borne epidemics remains extraordinarily high. From 1923 to 1945, for example, milk alone was responsible for almost a thousand recorded outbreaks of a variety of diseases affecting more than 40,000 people in the United States, a country that prides itself in particular on the sanitary quality of its milk supply. At that, many outbreaks undoubtedly were not reported. Education of the public in health will be found essential to the suppression of such occurrences.

Healthful housing remains one of the great challenges of the future. Solar heating of water and of dwellings may well come into use within our time.

It is true, finally, that the boon of sanitation has so far been vouchsafed to but a small fraction of the peoples of the world. As Wycliffe Rose, director of the Rockefeller Sanitary Commission which was to become the International Health Division of the Rockefeller Foundation, insisted, "Unless public health is conceived in international terms, the strategic opportunity of our generation will be lost."

Industrial Sickness Absenteeism

By W. M. GAFAFER, D.Sc.

First Two Quarters, 1951

A seasonal trend is recognizable in industrial absenteeism for the first two quarters of 1951.

The over-all rate for the winter months (1951's first quarter) is 168.4 absences per 1,000 male workers, representing a 29-percent increase over the 1:50 rate of 130.4 for the same period. Contributing to the rise is a 47-percent increase in the rate for

the respiratory group, with influenza and grippe the leading cause.

In warmer weather, absentee rates drop. There is more similarity between 1951 and 1950 second-quarter rates. Of interest again are influenza and grippe with the 1951 second-quarter rate one-third less than the first quarter.

A review of the respiratory group of diseases by corresponding quarters for 10 years, 1942-51, shows the 1951 first-quarter rate 15 percent above its 10-year mean and the second-quarter rate 8 percent below its mean.

The tabular data below, on 8-day or longer disabilities, cover approximately 170,000 male workers in in-

Dr. Gafafer heads the statistical services for the Division of Occupational Health, Bureau of State Services, Public Health Service. He continues here the series of industrial morbidity reports begun by the Public Health Service in 1920. An index of the entire series and the 1950 report appeared in the weekly Public Health Reports, November 23, 1951.

dustry and are based on periodic reports from industrial sick benefit associations, company relief departments, and group health insurance plans.

Absences per 1,000 male employees by cause (annual basis)—sickness and nonindustrial injuries disabling for 8 consecutive days or longer—first and second quarters, 1951¹

Insecticides and World Health

WHO Expert Committee on Insecticides

By SAMUEL W. SIMMONS, Ph.D.

The World Health Organization is a specialized agency of the United Nations and represents the culmination of efforts to establish a single intergovernmental health agency. It is the first intergovernmental institution to adopt the term "world" as part of its title. Disease knows no frontiers, and anything less than world action not only may deprive one nation of the benefits of WHO but may endanger the health of all member states.

WHO had its origin in the proposal, made at the United Nations Conference held in San Francisco in 1945, that a specialized agency be created to deal with all matters relating to health. In 1946, representatives of 61 governments met at the International Health Conference in New York, where they drafted and signed the WHO constitution and established an Interim Commission to serve until the constitution could be ratified by 26 member states of the United Nations. The constitution came into force on April 7, 1948; the First World Health Assembly met in Geneva in June 1948; and on September 1, 1948, the permanent organization was established.

The work of WHO is carried out by three organs: (1) the World Health Assembly, the supreme authority, to which all member states send delegates; (2) the Executive Board, the executive organ of the Health Assembly, con-

sisting of 18 persons designated by as many member states; and (3) a Secretariat, under the Director-General.

During the first few months of the existence of WHO, plans were prepared and operations were begun for launching offensives against disease. Expert committees, made up of international experts, advised the Director-General on the planning of immediate and long-term programs for improving world health.

Malaria, which still attacks, incapacitates, and kills millions of people in many parts of the world, but which lends itself to effective new measures of prevention and treatment, was one of the first diseases to which WHO gave special attention. The Interim Commission recognized that the problem of malaria was sufficiently urgent and important to warrant immediate action; an Expert Committee on Malaria was therefore established.

Committee Established

The Expert Committee on Malaria, at their second session in Washington, D. C., May 19-25, 1948, recommended that an Expert Committee on Insecticides be set up to specify international standards for insecticides and their formulations, to stimulate the development of standard spraying equipment on a regional basis, and to deal with all other questions relating to the proper use of insecticides. In response to these recommendations, an Expert Committee on Insecticides was established.

The original committee consisted of three members. In May 1950, however, the World Health Assembly authorized the appointment

Dr. Simmons is the chief of the technical development branch of the Communicable Disease Center, Public Health Service, Atlanta, Ga., and is a member of the Expert Committee on Insecticides of the World Health Organization.

of an expert advisory panel, from which a small number of experts are drawn to attend each meeting, depending upon the subjects to be considered.

First Session

The Expert Committee on Insecticides held its first session in Cagliari, Sardinia, May 10-15, 1949 (1). This choice of location afforded members the opportunity of gaining first-hand knowledge of the work being carried out in Sardinia under the joint auspices of the Italian Government and the Rockefeller Foundation (Ente Regionale per la Lotta Anti Anofelica in Sardegna—ERLAAS) in freeing the island of malarial mosquitoes by means of insecticides.

In addition, the committee was able to study the measures developed for preventing the reinfestation of the island from sea or air. Therefore, this group was in a position to make suggestions to the Expert Committee on International Epidemiology and Quarantine for the drafting of WHO regulations on the disinsectization of ships and aircraft.

The terms of reference of the committee were the following:

1. To advise the Expert Committee on Malaria regarding specifications of international standards for insecticides and their formulations for use against vectors of the disease, and of standard spraying equipment for malaria control and its adaptability to regional conditions.

2. To draw up a standard method of disinsectization of ships and aircraft, to be submitted to the WHO Expert Committee on International Epidemiology and Quarantine for consideration in the drafting of WHO sanitary regulations.

3. To make recommendations concerning measures that might be given general application for the prevention of the introduction of anophelines into areas free or freed from them.

The work of the committee at this meeting included the drafting of specifications for DDT. Specifications used in the United States and the United Kingdom for commercial DDT were utilized as a basis for these specifications. In view of the number and diversity of insecticidal preparations and the paucity of

knowledge concerning many of the new ones, it was impossible to fix specifications for other insecticides at that time.

The committee restricted itself to laying down the general requirements which should be satisfied by the various types of both compression and hand sprayers, since it was considered that it would be impracticable to market a single model suitable for use in all regions of the world and complying with all requirements. The draft specifications referred to the materials utilized, capacity, and weight, as well as to certain points relating to the construction of the different component parts of the sprayer. Several technical improvements were recommended.

With reference to the disinsectization of ships, the committee adopted in principle the regulations, drawn up by ERLAAS, which were intended to prevent the reintroduction of anophelines into the island of Sardinia. These regulations provided essentially for antianopheline treatments of all ships arriving in Sardinia from specified areas. The committee also had the opportunity of attending disinsectization operations carried out aboard a cargo vessel and of judging the efficacy of the methods recommended. The disinsectization of a cargo vessel of 2,000 tons takes 1½ hours.

The committee was of the opinion that disinsectization of ships and aircraft when carried out efficiently constituted a safeguard against the introduction of anophelines. It was thought that the same methods should be considered for road traffic whenever necessary. However, the application of disinsectization measures, by quarantine services at ports and frontiers, can never insure complete protection; it is essential that systematic campaigns against anophelines be instituted in areas where malaria is endemic and that surveillance be continued in those areas which have been freed from the pests, so that immediate steps may be taken in the event of the accidental introduction or reintroduction of the insects. In regions which have been freed from anophelines, the use of residual insecticides for controlling domestic insects is an effective means of destroying introduced mosquitoes.

The committee also took the opportunity to contradict certain rumors which had been cir-

culated concerning the toxicity of DDT to man and mammals, and considered the exchange of literature and information and the free flow of insecticides among nations.

Second Session

At the second meeting of the Expert Committee on Insecticides, held in Geneva, October 4-11, 1950 (2), the primary topics of discussion were the disinsectization of aircraft and ships and specification for insecticides and equipment. Other problems considered included the prevention of the reimportation of anophelines into areas freed of this mosquito and the free international flow of insecticides. A joint session was held with the Expert Committee on International Epidemiology and Quarantine to agree on recommendations for disinsectization of ships and vessels in international services.

Recommendations for the disinsectization of aircraft were considerably changed from the ones made at the first session. It was felt that the actual disinsectization procedures then in force were not effective, and that treatment of passenger planes with insecticides was being done in a perfunctory manner. Passengers, in many instances, are not amiable to being exposed to an effective dosage of an insecticide, and for this reason many of the airlines are reluctant to employ adequate treatments. It was felt that disinsectization should be carried out before take-off, with all luggage and/or freight loaded, but without passengers. All ventilators and exterior apertures should be tightly closed during spraying and for at least 5 minutes afterwards. If for any reason, passengers and/or crew have to disembark and re-enter the plane after treatment, the spray operation may be repeated at the discretion of the health authority. If adequate disinsectization is not carried out before departure, it may be done with passengers and crew aboard before the plane is landed. However, the disinsectization of planes without passengers aboard is desirable since this permits the use of more effective insecticides and the application of heavier dosages. This procedure may be a step toward fulfilling the requirements of both agriculture and public health procedures.

In addition to disinsectization procedures, antimosquito measures around airports should be rigidly carried out and a system of inspection set up to assure that this is done. It is desired that WHO be kept up to date on information relative to sanitary conditions, including presence or absence of vectors of disease around airports which are open to international traffic.

With reference to disinsectization of ships, it was again considered that antimosquito sanitation of seaports was essential. The committee recommended that the routine treatment of ships arriving in ports in areas declared free of vectors should be abandoned and replaced by routine inspection. Of course, in very small craft, routine treatment is often more economical and less time consuming than inspection. The committee pointed out that since ordinarily treatment will be carried out only on infested vessels, space-spraying may be more appropriate than spraying for residual-deposit effect; however, for ships in regular and frequent services between infested and free ports, residual treatment would probably be the method of choice.

As a space spray for use in the disinsectization of ships, the committee recommended an aerosol of pyrethrins and DDT dispensed at the rate of 10 gm. per 1,000 cubic feet of inclosed space. For residual treatment, DDT sprayed at the rate of 200 mg. per square foot was advised.

The following specifications for insecticides were recommended:

1. Revision of specifications for technical DDT.
2. Specifications for DDT wettable powder concentrates of 50 percent or over.
3. Tentative specifications for DDT emulsion concentrate of 20 percent and above.
4. Specifications for technical benzene hexachloride (12-14 percent gamma-isomer BHC).
5. Specifications for gamma-isomer benzene hexachloride concentrates of 90 percent and above.
6. Specifications for technical benzene hexachloride wettable powder concentrates (50 percent technical BHC and over).

7. Tentative specifications for technical agricultural grade and clarified grade chlordan.

8. Guidance information for the purchase of methoxychlor.

In the matter of equipment, specifications were formulated for compression and hand sprayers as established at the first session of the committee. In addition, preliminary specifications for stirrup pumps, which are extensively used in some parts of the world in malaria control activities, were set forth.

The hope was expressed that WHO would meet with success in its endeavors to insure a free flow of insecticides and the waiving of customs duties.

The recommendations of the Expert Committee on Insecticides, when approved by the Executive Board, become official for use by all member nations of WHO. They do not in any way hamper improvements in techniques or equipment by member nations, but they do insure that nations with insufficient technical information are given proper guidance in conducting their vector-control programs.

There can be no doubt that the recommendations of the committee have advanced the effectiveness of malaria control in many countries, and future meetings will augment the information already available to backward areas. It is hoped that eventually recommendations of the expert committee will encompass all important vector-control problems throughout the world.

A necessary function in accomplishing this feat is a continuing and expanding program of research. The rapid increase in the use of insecticides has given rise to many problems not originally envisaged by either the health authorities or the insecticide manufacturers. Furthermore, practical application in the field of insecticides has gone far ahead of fundamental research. With these considerations in mind, the Expert Committee on Insecticides, at its second session, recommended "that WHO draw the attention of member governments to the fact that, for the practical continuation of disease-vector-control throughout the world, an increase in fundamental research work has become even more imperative than heretofore."

Third Session

The third session of the Expert Committee on Insecticides met at Savannah, Ga., July 30 to August 4, 1951 (3). The recommendations set forth at this meeting, however, have not been approved by the Executive Board of WHO and, therefore, cannot be reported in detail at this time.

In general, the committee established specifications for stirrup pump type sprayers, hand and rotary dusting apparatus, and certain types of spray hose. Specifications were also established for spray control valves and hose connections, and a specification chart for compression sprayers was approved. This chart will enable those selecting sprayers to determine the attributes of various commercial models with reference to their compliance with WHO specifications.

One of the most valuable pieces of work accomplished by the committee was the establishment of standard nomenclature for types and parts of spraying equipment. The international adoption of these recommendations will alleviate much confusion relative to the purchase and use of spraying equipment. It is sincerely hoped that all governments and manufacturers will adopt these recommendations after their approval by the Executive Board of WHO, and that future meetings of the Expert Committee will augment the present list of definitions to keep pace with the development of spraying equipment.

"The attainment by all peoples of the highest possible level of health" has become the watchword and the goal of WHO, and the Expert Committee on Insecticides is a potent factor toward accomplishing this end.

Insecticides

and

Rodenticides

1952 Recommendations for use

Laboratory and field investigations to determine the effectiveness and toxic hazards of various economic poisons which offer promise for use in communicable disease control have been conducted for several years by the technical development branch of the Communicable Disease Center. The results of these investigations and a review of work done by other research agencies have been used as a basis for recommendations on materials, dosages, and application techniques for use in field operations.

The rapidly changing status of resistance to insecticides exhibited by some insect species makes it difficult, if not impossible, to make general recommendations for their use in all areas. Consequently, it will be necessary for operators in any given area to adapt these recommendations to the situation at hand.

Mosquito Control

During the past year, there have been indications from several scattered areas in the world that some species of *Anopheles* are developing resistance to DDT. Some evidence has been developed by workers of the Tennessee Valley Authority that *Anopheles quadrimaculatus* may be developing resistance to DDT in some localities in which DDT has been used continuously for more than 5 years. However, in general this species does not appear to have de-

veloped resistance to DDT to a degree which would significantly affect control operations. The continuation of previously adopted procedures for the control of *A. quadrimaculatus* is recommended for 1952, namely, the use of 5-percent DDT emulsion residual sprays in homes to control the adult mosquitoes and the use of 0.05 pound of DDT in 1 gallon of fuel oil per acre to control the larvae; DDT at the rate of 0.05 to 0.10 pound per acre, applied as a 20-percent solution in methylated naphthalenes, such as Velsicol NR70 or Sovacide 544B, is recommended for airplane treatment; and a 5-percent DDT emulsion or a 5-percent DDT oil solution for outdoor space spraying to control adult mosquitoes.

The only known mosquito vector of disease which appears definitely to have developed a high degree of resistance to insecticides in the United States is *Culex tarsalis* in California. Observations by the Bureau of Entomology and Plant Quarantine of the United States Department of Agriculture indicate that in some localities this species has developed varying degrees of resistance to a number of chlorinated hydrocarbons, including DDT, toxaphene, lindane, aldrin, and heptachlor applied as space sprays. Although no specific recommendations can be made for control of the resistant strains of this species, DDT-DMC combinations, and perhaps other DDT-synergist combinations as they become available, may be used on a field trial basis. Combinations of DDT with DMC (*p*-dichlorodiphenyl methyl carbinol) at ratios from 5:1 to 20:1 have been effective as space sprays against field strains of DDT-resistant houseflies.

DDT Substitutes

Salt-marsh mosquitoes in several areas are unquestionably resistant to DDT and other insecticides. As an initial substitute against DDT-resistant strains, the Bureau of Entomology and Plant Quarantine found lindane at 0.1 pound per acre or technical BHC (benzene hexachloride) at 0.4 pound per acre, both applied as fuel oil solutions from airplanes, to be an effective larvicide. During 1951 poor results were obtained with BHC in some localities. Field trials of DDT-DMC or other DDT-synergist combinations are recommended when salt-marsh or other pest mosquitoes have become resistant to the chlorinated hydrocarbons. Where resistance is not a factor, DDT remains the insecticide of choice.

Against some species of pest mosquitoes which have not developed resistance to DDT, barrier-strip residual spraying with DDT around the outside of individual premises has given effective control. In the Savannah, Ga., area, preliminary tests using 1-percent DDT emulsions applied to the outside of houses, and to shrubbery, grass, and other vegetation for a distance of approximately 100 feet around the houses, gave satisfactory reductions against the common species of salt-marsh mosquitoes for about 3 weeks. It is recommended that similar procedures be used experimentally in situations where other control measures are not more feasible, as for example to protect individual premises or groups of premises in irrigated agricultural areas.

Residual larviciding with technical BHC (12-percent gamma iso-

This paper was prepared by the technical development branch of the Communicable Disease Center, Public Health Service, Savannah, Ga.

mer) emulsions at the rate of 1 pound per acre (in gallons of finished spray per acre applied in the same manner as oil solutions) has given satisfactory mosquito control in small, land-locked, fresh-water ponds against a variety of anopheline and culicine species for periods ranging from 5 to 8 weeks. No damage to fish was observed during 3 consecutive years of treatments with BHC, during which five treatments were made each year spaced at approximately 5-week intervals between April and October for a total of 15 1-pound-per-acre applications during the 3-year period. There was some indication of off-taste in fish from one of the treated ponds in which unusually low water levels had prevailed at the end of the third year of treatment. It appears that technical BHC (12 percent gamma isomer) can be applied safely as emulsions at the rate of 1 pound per acre at approximately 5-week intervals without damage to fish for 3 consecutive years. This procedure is recommended for residual larviciding where fish are present.

When fish are not present, effective control for periods ranging from 3 to 6 months has been accomplished near Savannah by residual larviciding with DDT emulsion at the rate of 3 pounds per acre (in 2 gallons of finished spray), using the method usually employed in applying oil-mist sprays as mosquito larvicides. *This treatment is totally destructive to fish present in the ponds at the time of treatment, and should not be used where fish are present.*

Dieldrin applied as an emulsion concentrate or a wettable powder suspension at the rate of 1 pound per acre will also prevent mosquito breeding for more than 1 year. *However, it is completely destructive to certain other aquatic life, and should not be used except in emergency or in other unusual circumstances.*

Fly Control

Residual Sprays

In most areas of extensive use of residual sprays, houseflies have be-

come highly resistant to DDT and in some instances to several other chlorinated hydrocarbons. Unfortunately, the work of the past year with residual insecticides has produced very few promising leads for the solution of this problem.

DDT is still the insecticide of choice in areas where houseflies remain susceptible to it, except in dairy barns and other places where it may contaminate milk. A 5-percent emulsion or suspension applied at the rate of 4 ml. of spray per square foot of treated surface area is recommended for general use. Where outdoor treatments are required, the addition of pine gum rosin to give 2 percent rosin in the finished spray increases the residual effectiveness of the DDT.

Dieldrin applied as a 0.625-percent emulsion is recommended as an outdoor residual spray for use by trained personnel in organized fly control programs in areas where DDT-resistant flies may still be susceptible to this compound. However, fly populations may develop resistance to dieldrin in less than one season and in some areas it has already become ineffective through the development of such resistance. The precautions which have been recommended in the "Operational Memorandum for Dieldrin," issued by the technical development branch of the Communicable Disease Center, should continue to be observed in dieldrin spraying operations.

Chlordan is recommended for selective spot treatment inside dwellings and on porches, insides of outbuildings, and other locations relatively protected from the weather, in areas where flies have not yet become resistant to this insecticide. A 5-percent emulsion is recommended for this general use, except that formulations used within dwellings should not contain more than 2.5 percent chlordan.

Lindane applied at the rate of 25 mg. per square foot, or methoxychlor at 200 mg. per square foot, is recommended for use in dairy barns, feed barns, and other places where the use of other chlorinated hydrocarbons might contaminate milk. However, neither of these may be expected to give the degree of control

originally achieved with DDT residuals, particularly where flies are already highly resistant to DDT.

Dilan is suggested as a residual spray for experimental testing on operational fly control programs. Current information indicates that 2.5- to 5-percent suspensions of water-wettable dilan are effective as a residual spray against DDT-resistant flies. However, there is already evidence from laboratory studies that flies may develop resistance to dilan within a relatively short time.

Larvicides

The use of larvicides may be desirable for fly control in certain situations, as in the treatment of dirty garbage cans and privies or of concentrated fly breeding areas such as at stockyards or chicken farms. Several of the chlorinated hydrocarbons are effective fly larvicides, but their use may result in the development of the same resistance encountered when they are used as adulticides. Among the more promising larvicides for general use are chlordan, lindane, and BHC. Dieldrin and aldrin are also effective fly larvicides. These materials should be applied at the same dosages per square foot as recommended for residual sprays. In general, it appears desirable to dilute the residual spray emulsions or solutions to three to five times their original volume in order to provide better penetration of the larvae breeding medium. The same precautions in applying dieldrin or aldrin as larvicides should be observed as when dieldrin is used as a residual spray.

In small-scale field tests, applications of paradichlorobenzene crystals (PDB) at the rate of 2 oz. per garbage can has controlled fly breeding for 1 to 2 weeks. This procedure is suggested for trial in areas where flies are resistant to other types of larvicides.

Space Sprays

When flies have become resistant to the aforementioned materials applied as residual sprays or larvicides, space sprays are the only alternative for chemical control. Selective treatment of night-time resting places with space sprays appears to be a

promising approach because of the concentration of flies in limited areas at night. In urban areas, houseflies and the more common blowflies generally rest at night in the lower branches of trees and in bushes, grasses, and weeds. During cool weather, houseflies tend to seek the protection of outbuildings. Species of *Drosophila* appear to rest predominantly in privy pits or buildings. In rural areas, the inside of unscreened dwellings is a favorite resting place. On premises with screened dwellings, the flies rest on porches and in animal shelters during cool weather, and on the lower branches of trees and on shrubs in warm weather (minimum daily temperature 70° F. or above). Since temperatures and local environmental conditions affect the flies' choice of nocturnal resting place, limited local surveys should be conducted as a guide to night-time space spraying operations.

Combinations of DDT with DMC at ratios ranging up to 20:1 have given effective kills when applied as space sprays against field strains of DDT-resistant flies. Emulsions or fuel oil solutions of this combination, using 5 percent DDT, may be used as space sprays for fly control. Other DDT-synergist combinations are under investigation.

In small-scale field tests 2.5-percent emulsions of dilan applied as outdoor space sprays at dosages of 0.05 pound per acre were highly effective against DDT-resistant flies. The emulsions were prepared with technical dilan in the same manner as with DDT. It is recommended that technical dilan be utilized at 2.5-percent concentrations in operational programs where flies are resistant to other insecticides.

Among the most reliable and least toxic to humans of the space sprays are pyrethrum formulations, which are usually used in indoor space sprays and are the insecticide of choice for this purpose. Pyrethrum formulations are used in combination with synergists such as piperonyl butoxide, in emulsions or oil solutions containing from 0.05 to 0.1 percent pyrethrins and 0.5 to 1.0 percent of the synergist. However, they are currently in short supply

and are too expensive for general large-scale use in fly control.

Where flies are still susceptible to BHC, a 5-percent technical BHC (12 percent gamma isomer) or a 2-percent lindane emulsion is recommended as an outdoor space spray for use against flies resistant to DDT and chlordan. Where odor is not a factor, the technical BHC is favored because it is cheaper. The development of fly resistance to these compounds may be expected if they are used regularly.

A 2.5-percent emulsion of chlordan may be used as an outdoor space spray against DDT-resistant flies. Houseflies in some areas have developed resistance to space sprays of this material. Housefly resistance to it may be expected to appear if it is used continuously for fly control.

Sanitation

The development of housefly resistance to many different types of insecticides has refocused attention upon the importance of sanitation as a fly control measure. There is universal agreement that sanitation should be exploited to the fullest degree possible in conjunction with the use of chemicals for fly control. Insecticides are more than ever a supplement to sanitation rather than a substitute for it. The value of screening as a fly control measure is also worthy of re-emphasis.

Flea Control

In field tests conducted over a period of 3 months, a 5-percent DDT dust has been found to be as effective as a 10-percent dust when applied to rat runs and harborage areas for the control of the oriental rat flea. The 5-percent dust has been used on some operational programs. However, most operators have preferred to use the 10-percent formulation, particularly where it was desirable to control other ectoparasites more resistant to DDT, for example, the cat flea.

A 10-percent chlordan dust is recommended for use in controlling soil infestations of cat and dog fleas. A single application of this material has given effective control of infestations, whereas repeated applica-

tions of DDT would have been required.

Roach Control

A 2- to 2.5-percent emulsion or oil solution of chlordan is recommended for spot spraying for roach control in bomes. Such treatment should be confined to limited harborage areas, such as space behind baseboards, in cracks and crevices, and around openings through which roaches may gain entrance from the outdoors. Over-all applications of chlordan should not be made in bomes.

Rodenticides

The possibilities of rodent control appear to be more encouraging than ever before, for, unlike insects, rats do not seem to have developed resistance to poisons.

Warfarin

The most recent addition to the rodenticides, warfarin, maintains its early promise. It is the first effective slow-acting rodenticide, and its characteristics—(a) failure to induce bait shyness, (b) necessity for repeated ingestion if control is to be achieved, and (c) relatively small hazard to man and useful animals compared to the hazard offered by most other effective rodenticides—make it the first effective residual rodenticide ever developed. According to results of tests completed during the past year, the warfarin susceptibility of the different species of commensal rodents differs. This has been confirmed by laboratory field studies. Therefore, in the interest of economy and safety, it appears only reasonable to use the lowest bait concentration consistent with the most effective control.

Dependable control of the roof rat, *Rattus rattus*, requires the use of a concentration of 0.250 mg. of warfarin per gram of bait (0.025 percent). However, field tests have shown that a concentration of 0.050 mg. per gram (0.005 percent) is effective for control of the Norway rat (*Rattus norvegicus*). Mice react in the same general way as Norway rats although they show more individual variation. There is

evidence that under certain conditions Norway rats may be controlled a little more rapidly, though no more surely, by use of bait containing 0.100 mg. of warfarin per gram of bait instead of a concentration of 0.050 mg. per gram. There is a real opportunity for those associated with city and county programs to determine by careful operational observations which of these two concentrations is more desirable for use in organized control campaigns carried out by personnel who have received some training in rodent control but who make no claim to be experts in the field. However, if the species of rat concerned is not definitely known, the 0.025 mg. per gram concentration should be used.

Warfarin may be used for initial rodent control under essentially all conditions, using a minimum baiting period of 2 weeks. In addition, consideration should be given to establishing bait stations for permanent control of rats in places which are subject to reinfestation. Two years of experience has shown that Norway rats can be controlled in non-ratproof buildings so long as poisoned bait is available. No difference in this residual effectiveness of the 0.100 and the 0.050 mg. per gram bait concentrations was observed. The bait stations were inspected approximately every 6 weeks and fresh poisoned bait was supplied.

ANTU

ANTU still holds a definite place as a quick-acting poison for the Norway rat. Its use to reduce large populations rapidly may be followed by the use of warfarin to achieve complete and lasting control. ANTU should not be used against the same population more often than about once a year. It induces a very persistent bait shyness in rats and this property makes it ineffective for repeated use against the same population. It is not effective for the control of roof rats or mice. Its safety record is good so that it may be used in residences and food-handling establishments.

Sodium Monofluoroacetate (1080)

Sodium monofluoroacetate (1080) is still the most effective, fast-acting rodenticide, but its extreme toxicity to man and animals requires that it be used only on certain types of premises and only by carefully trained crews. The precautions necessary for the safe use of 1080 are numerous and involved. They are described in "Operational Memoranda on 1080," issued by the technical development branch of the Communicable Disease Center.

Baiting Problems

In tests in Savannah, corn meal has proved to be the most readily

accepted cheap bait. In general, any available cereal bait is recommended for use. It is worth emphasizing again that under certain conditions it is very difficult to get rodents to take bait; for example, where food is available in great variety and abundance, as in some warehouses. Such conditions constitute baiting problems, a term which implies that the origin of the problem is not in the particular poison used but in the ecology of the animals themselves. Obviously, in testing any given rodenticide formulation, it is necessary to make sure that apparent failure of the formulation is not caused by baiting problems. These problems can be solved efficiently only through extensive knowledge of the habits of the rodents. They do not occur more frequently when simple cereal baits such as corn meal are used than when complex bait mixtures are used.

Sanitation

The importance of sanitation, including proper garbage disposal, food storage, harborage elimination, and ratproofing must be emphasized. Sanitation is essential to the permanent control of commensal rats and mice and the use of rodenticides should be regarded as supplementary to sanitation.

Conference on Aging

"Housing the Aging" will be the topic for a conference to be held in Ann Arbor, Mich., July 24-26, 1952, under the co-sponsorship of the University of Michigan, the Michigan State Medical Society, the Committee on Aging and Geriatrics of the Federal Security Agency, and the Housing and Home Finance Agency.

The 3-day conference will consider the housing needs of healthy, chronically ill, and disabled older people. Types of housing and living arrangements, architectural designs and costs, hygiene and safety standards, social and economic aspects of housing, and auxiliary services will be discussed.

Registration information may be obtained by writing to Dr. Wilma Donahue, Institute for Human Adjustment, Room 1510, Rackham Building, Ann Arbor, Mich.

Mosquito Control in Water Resource Projects

These remarks by Dr. Saxvik, and those of Dr. Rowe which follow, are part of a discussion before the 52d meeting of the Missouri Basin Inter-Agency Committee held at Bismarek, N. Dak., October 24, 1951. The committee, created in April 1945, provides a means through which field representatives of Federal agencies exchange information and coordinate activities—among themselves and with the Missouri Basin States—in the preparation of reports and in the planning and execution of works for the control and use of the waters of the basin and for the development of the basin's resources.

I. Prevention vs. Abatement

By R. O. SAXVIK, M.D., M.P.H.

Today, we in this country have fashioned for ourselves the highest standard of living yet known to man. We are no longer content to exist in the midst of an unsanitary, dangerous environment. The fight for new remedies and treatments for control of disease is constantly going on. Advances in sanitation which have contributed to the convenience and comfort of the individual have been promptly adopted. Sanitary measures must interpose a barrier in some channel of infection to block the path between the carrier on the one hand and susceptible persons on the other.

Public thinking is on the threshold of a new concept of environmental health. Mosquitoes have been proved to be vectors of disease, but the constant annoyance caused by these insects can seriously impair physical and mental well-being. We have the know-how for controlling mosquitoes, and even for preventing their prop-

agation. We are not going to sit idly by while subjected to the annoying and sometimes dangerous attacks of hordes of mosquitoes.

The Deputy Surgeon General of the Public Health Service, Dr. W. Palmer Dearing, stated on October 12, 1950 that "There are, however, other public health concerns which justify State stipulation as to mosquito control in water impoundment and irrigation projects. The viral encephalitides (forms of 'sleeping sickness') of which there are three major types, endemic and occasionally epidemic in the United States, are transmitted to man by mosquitoes of various species. Human encephalitis is a dangerous disease attacking man in a manner similar to poliomyelitis."

Dr. Dearing, in the same statement, said, "It is our conviction that pest mosquitoes should receive more attention from health authorities than they have in the past. Public health has become more than the absence of disease. Physical efficiency and comfort, on which mental equanimity depend to a substantial degree, may be seriously disturbed by the continued annoyance of pestiferous mosquitoes which may or may not have disease-transmit-

Dr. Saxvik is the State Health Officer for North Dakota and chairman of the committee on environmental sanitation of the Association of State and Territorial Health Officers.

ting potentialities. This principle has already been recognized by the Departments of the Army and of the Air Force in the development of pest mosquito control methods to be used for the protection of troops in the Arctic."

Mosquito Control

Mosquito control undertaken because of public demand usually becomes the responsibility of the local health department. After the problem has been allowed to develop, control by modern methods is both difficult and expensive. More public dollars are required and a greater potential hazard exists. In California, the annual expense for mosquito abatement alone is now nearly 2 million dollars. Where irrigation is extensive, typical costs per year, by counties, are: Alameda, \$108,000; Fresno, \$94,976; and Merced, \$166,668. These figures do not reflect the cost of a complete program of correction. It is estimated that effective control of the overall problem would cost approximately 10 million dollars per year. Much prevention could have been effected at a nominal portion of this cost. In the Milk River Area of Montana, Malta and Glasgow, towns of 2,500 and 4,000 population, respectively, have found it necessary to begin mosquito control, and have annual budgets of \$3,000 and \$2,000 for this work. They are too late to prevent mosquitoes so they are beginning the costly cure. The same situation exists in several States where irrigation is practiced. Experience has demonstrated that through active and cooperative efforts of all the various agencies and groups engaged in water development work, a great many problems will be avoided and others will be minimized if careful planning for mosquito control precedes construction work.

Encephalitis Vector

Mosquitoes have been shown to transmit at least five strains of encephalitis—western and eastern equine, St. Louis, California, and Japanese B. The Missouri River Basin has representatives of the species of mosquitoes that carry these five strains. Also, several unidentified viruses associated with mosquitoes in nature have been found through recent research.

Pathogenicity of these viruses to human beings remains to be determined.

In North Dakota, during the past 5 years, there have been 285 cases and 29 deaths due to encephalitis. During 1936–40 there were 160 cases with 60 deaths, while in the period 1941–45 there were 1,215 cases, with 187 deaths. This last period includes the epidemic of 1941 when in 1 year, there were 1,101 cases resulting in 134 deaths. During this epidemic, the case incidence was 171 per 100,000 population with a mortality rate of 20.8 per 100,000 population, indicating that encephalitis is a real problem in North Dakota.

Serologic Examinations

The Rocky Mountain Laboratory of the Public Health Service, at Hamilton, Mont., has been examining a series of routine blood samples submitted to the North Dakota State health department laboratories for examination of antibodies of western equine encephalomyelitis in human beings. A total of 2,194 serums was examined; 356 showed a positive result. Samples from all 53 counties in the State were included. On a percentage basis, this was a 16.2 percent positive sample, or one out of six serums examined. We fully realize the seriousness of this disease when we consider that one out of six residents of North Dakota has had encephalitis in varying degrees of severity at one time or another, if the results of the tests of blood samples are representative of the extent of infection in residents of the State.

As yet, there is no known specific therapeutic treatment for virus encephalitis. The importance of prevention is immediately obvious: prevention is possible only through the control of the mosquito vectors. There is presumptive epidemiological evidence that poliomyelitis may possibly be transmitted by biting insects, perhaps mosquitoes, and if by mosquitoes, then by species widely prevalent in this area.

A study of the outbreak of encephalitis in Barnes County in 1949 lends support to this evidence. During a brief period, three distinct types of central nervous system illness occurred. Two of these were caused by known diseases—poliomyelitis and western equine en-

cephalomyelitis—but antibodies for the recognized neurotropic viruses present in this area were not found among the greater number of ill persons, indicating the existence of a third undetected and unidentified virus whose mode of transmission is unknown.

Equine Encephalitis

While encephalitis in equines is not considered a public health problem, the disease has economic importance and is of considerable concern to agricultural interests. The number of cases in horses is steadily dropping, which can be accounted for by the 300-percent reduction of the horse population during the last 15 years. Pest mosquitoes are of economic importance to the dairy and stock farmer. It has been proved that milk losses are considerable on dairy farms during the mosquito and fly season. Beef cattle, if bothered by pest mosquitoes, fail to gain weight or to develop properly. In considering the over-all benefits of mosquito abatement, these agricultural benefits must be taken into account.

Control Program

The North Dakota State Department of Health has initiated a mosquito survey and control program. Through the cooperation and financial aid of the Public Health Service an entomologist has been obtained to work with Federal, State, and local agencies toward carrying out mosquito-prevention measures during the planning, construction, and operation of water resources projects. The entomologist will evaluate present habitat and species found in the State, and will seek to determine what disease-carrying species are present. The changing ecologic conditions will also be studied to evaluate the future mosquito problem.

It is the sincere hope of all health officials that future water resources development projects include antimosquito precautions and practices. Efforts aimed at the elimination or minimization of health hazards due to mosquito vectors would do much to control disease trans-

mission, and at the same time would tend to reduce the density of pest mosquitoes. If this is done, another step forward in the improvement of our environment will have been made.

Control and Poliomyelitis

It has been observed that in the past few years a high percentage of cases of poliomyelitis have come from rural areas where DDT and other insecticides are not widely used for control of mosquitoes. Although there is no positive data available, workers in the field have observed a lowering of the incidence of virus diseases in urban areas where DDT is used to control mosquitoes. This has been true in North Dakota, where a majority of cases of poliomyelitis and encephalitis have occurred among rural residents, rather than in the larger communities where mosquito control has been practiced.

Data show that many species of animals serve as hosts to the viruses, with a widespread and complicated infection chain in nature which involves arthropods, birds, and small mammals. Data bearing upon mosquito transmission of the virus are sufficient to propose that antimosquito measures are the best method of control at present. A barrier between the carrier and susceptible persons must be established by adequate mosquito control. It is the only known method for controlling encephalitis and perhaps other virus diseases. North Dakota now has a considerable mosquito problem due to large areas of stagnant water in potholes and low-flow streams during the warm summer months. The development of irrigation, if not properly constructed, will increase this problem. Water is a factor common to all outbreaks of encephalitis. Water determines where maximum populations of people will be found and where mosquito densities will be greatest. The encephalitis rate is now excessively high in North Dakota, and if we allow an increase in mosquito density, we will have a problem of increased magnitude. It is essential that present mosquito problems not be aggravated and that new ones not be created.

II. Insect Problems and Irrigation

By JOHN A. ROWE, Ph.D.

Water development in this country has produced a host of mosquito problems stemming from various types of projects. Some of these problems have come about through faulty construction while others are due to bad practices in the use or operation of projects. Mosquito problems associated with water development programs result from water standing too long on the surface of the ground, thus creating breeding places for mosquitoes. Until recently, neither the builders nor the operators of projects were fully aware of the nature and size of these mosquito problems and, hence, could not be expected to initiate measures to prevent them. Local, State, and Federal health agencies for several years have studied these problems in an effort to find practical methods for preventing and controlling mosquitoes.

Mosquito problems associated with storage reservoirs or other impoundments have been fairly well delineated through field studies. The results of these studies have been published in numerous technical papers. They are summarized in "Malaria Control on Impounded Water" (U. S. Government Printing Office, 1947). It is not desirable at this time to review water impoundment problems and the control measures which are thoroughly covered in this summary, but rather to describe briefly and discuss examples of major mosquito problems associated with irrigation.

Dr. Rowe, senior scientist with the Public Health Service, is assistant chief of the water resources section of the vector control and investigations branch, Communicable Disease Center, at Salt Lake City, Utah.

Irrigation of Pastures

In the Western States, probably the most serious mosquito problems result from the irrigation of native grass pastures and "wild" hay lands. The severity of these problems is well known to the inhabitants of the valleys of California and Utah, and to those of the valleys of the Milk River in Montana, the Platte River in Nebraska and Colorado, and elsewhere. The numbers of mosquitoes produced on these irrigated pastures reach astronomical proportions. In California, for example, one mosquito trap operated near an irrigated pasture for three nights collected nearly a gallon of mosquitoes. Mosquito-egg counts from pasture sod samples have shown that as many as 20,000,000 eggs of *Aedes nigromaculis*, a western pasture mosquito, may be present on an acre of irrigated pasture. These tremendous numbers of mosquitoes do not occur in only one or two broods each year, as may be the case in "dry land" areas, but a new brood is produced following each successive flooding of the pastures throughout the irrigation season.

Studies in the North Platte Valley and elsewhere show that a combination of factors produce the severe mosquito problem on these pastures and hay lands. In many instances the fields were not prepared to receive irrigation water, and consequently their surfaces are irregular and unlevel. Because of this, the irrigators must force tremendous amounts of water over the land in order to cover the high spots. Extensive areas covered to a depth of 18 inches may be observed regularly. In many instances, even where land is fairly level, huge amounts of water are literally poured onto the pastures. As a result of these practices, high-

way and railroad rights-of-way and large tracts of unused land are inundated during each irrigation turn. Over extensive areas of bottom pasture land the major drainage structures have deteriorated and become ineffective, and in most areas no drainage structures are evident for the removal of water from roadways or unused land, or for draining off excessive amounts of water from pastures.

These conditions over literally thousands of acres of native grass pasture have created choice ecologic habitats for several of the most predacious mosquito species in our western fauna. To the layman it appears also that the quality and productiveness of the land have been adversely affected.

The control of mosquito problems on irrigated native grass pastures cannot be accomplished unless the principles of "conservation-irrigation" are effectively applied. Because of established customs and habits, and because of the apparently abundant supply of irrigation water, in certain areas, the successful application of these principles to existing irrigated pastures will be difficult and will require the active cooperation of all agencies, groups, organizations, and farmers involved. The prevention of such problems on future irrigation developments, however, should be an easier task and one which, when successfully accomplished, should result in great public benefits. Unless the water development agencies and others concerned willingly attack this problem on existing and future irrigation projects, the States whose people utilize the projects ultimately will be forced to spend large amounts of public funds on an annually recurrent basis for artificial and difficult mosquito control measures as in California, Utah, and elsewhere. Otherwise the fullest potential productiveness of the projects will be retarded.

Seepage Areas

From the very beginning of irrigation in this country, seepage areas have been a major problem confronting the farmers, the irrigation companies, and the water- and soil-development agencies. To these groups "seep areas" mean reduced production, inefficient water distribution, water loss, and the depletion of desirable

qualities of the soil. Some regions report as much as 50 percent of the water diverted from streams or from storage reservoirs is "lost" to seepage, and in certain irrigation districts thousands of acres of seep land exist. Health agencies are concerned with seepage areas because of the mosquito problems involved. Available data indicate that many types of seeps, where the water actually reaches or covers the surface of the soil, produce extremely large numbers of *Aedes*, *Culex*, and *Anopheles* mosquitoes.

The control or prevention of seepage areas is a difficult and expensive task. In many instances it involves the treatment of canals and laterals to prevent water loss. In other instances, it requires closer attention to the water requirements of specific crops in order that seepage resulting from deep water percolation may be reduced. Statements have been made to the effect that because of downstream recoveries, water arising from "flowing seeps" is not entirely wasted. This may be true; nevertheless, these seepage areas represent acute mosquito problems which appear to be increasing in magnitude.

In present and future irrigation developments the anticipation of seepage problems is a major concern of the responsible water development groups. Structures to prevent seepage from canals and laterals should be installed where needed and surface water arising from deep percolation should be channeled and concentrated to the greatest possible extent.

Drainage

Major mosquito problems on irrigation projects often result from inadequate provisions for drainage. Field studies show that this is especially true on the older irrigation developments. When old irrigation developments are compared with new ones, progress in the drainage features of the project are readily recognized. The water development agencies responsible for this progress are to be complimented. For the most effective mosquito prevention, however, further progressive drainage actions are needed. On most projects, the extension of drainage provisions would go a long way toward eliminating mosquito problems cre-

ated by the wastage of water into highway and railroad rights-of-way and other waste areas. For instance, field data from studies of recently completed projects on certain grade A lands show that the only mosquito problems in these areas were those created by the wastage of water from cultivated fields. There is no doubt that if, during the construction phases of these projects, the basic drainage plan had been extended to include drainage of roadways and other waste areas, virtually mosquito-free projects would have resulted.

In overcoming this problem it is realized that the jurisdictions of groups other than the primary construction agencies are involved. These include units of State and local governments, private companies, and individuals. Nevertheless, it would seem that opportunities are presented during the planning and developmental phases of the projects for the discussion of these problems and for making basic provisions for such drainage extensions.

The conditions which have been described are examples of only a few major mosquito problems associated with the development and operation of irrigation projects. Many other situations are known which constitute significant problems in certain areas, such as (a) surface water due to overflow or leakage from poorly maintained irrigation distribution systems; (b) impoundment of water in natural drainage ways due to the faulty emplacement of drainage and other structures; and (c) residual water in irrigation structures such as siphons, turn-outs, and drops, and in secondary canals and ditches. Individually, these and other conditions may not seem to be very significant, but when they occur repeatedly throughout a project they collectively become problems of considerable magnitude. Because the water involved serves no useful purpose, it is considered wasted.

Preventive Program

In cooperation with State health departments, the Public Health Service, through its Communicable Disease Center, is developing a program to aid the various water development agencies and groups in preventing mosquito problems on future water development projects, and to reduce the severity of existing prob-

lems on completed projects. The effectiveness and success of this program depend to a large extent on the support and cooperation received from other groups or agencies. These include not only the Federal planning and construction agencies, but also units of State, county, and city governments; farm organizations; irrigation companies; and other water development groups.

The program is threefold: field investigations and research, cooperative basin-wide activities, and development of State programs.

Field investigations have been established in representative areas to determine, evaluate, and grade the factors which produce mosquito problems associated with water development programs and to develop and test field techniques and methods for overcoming these problems. It is hoped that certain additional field research studies can be initiated in cooperation with the research groups of other agencies. Investigations will involve both biological and engineering features.

The Public Health Service will carry out its responsibilities relating to mosquito problems in connection with basin-wide investigations and reports. The Public Health Service Drainage Basin Offices have initiated activities whereby the planning and construction agencies will be kept fully informed relative to major mosquito problems involved in water development programs. Reports of various agencies will be reviewed and the vector aspects will be called to the attention of the agencies concerned. Field surveys will be made of major representative units or projects, which are in the investigational stage of development, for the purpose of obtaining basic data which will permit the anticipation of vector problems. These surveys will be conducted in accordance with established Public Health Service policies.

Development and direction of activities relating to its own projects are, of course, the primary responsibility of the State. Where the development programs are more extensive and complicated, assistance may be possible through the loan of technical personnel to the State health departments. These men will be available to work on existing problems and will assist water development agencies working in

the State to prevent mosquito problems on future projects. The long-range goal is to assist in the establishment of sound, adequate programs in those States which have mosquito problems.

The program, in all its ramifications, is a positive one, to aid and assist in the fullest and

most beneficial development of our water resources. We hope that, through this program and with the cooperation of all interested persons and groups, the factors which have produced serious mosquito problems on water development projects in the past will be eliminated from the projects of the future.

Community Volunteers and Mosquito Control

By R. E. DORER

Volunteer mosquito control work by the residents of Stony Creek, Va., brought the town relief from the usual mosquito annoyance during the past summer.

The Stony Creek Woman's Club initiated and supervised the project, the school children did the inspection work, and the townspeople cooperated by eliminating mosquito breeding places on their premises.

The woman's club, seeking a youth activity it could sponsor in the community as part of a national club program, turned to the Virginia State Department of Health for advice on the feasibility of a mosquito control project.

In June 1951, the bureau of insect and rodent control in the department inspected and analyzed the conditions in the Stony Creek area, an agricultural community of approximately 400 people in the southern part of Virginia, 75 miles inland.

About a mile from town, there is a fresh-water marsh area of several acres. After checking on the mosquito species in the marsh, the surveyors decided the marsh could be disregarded as a primary mosquito source. Few mosquitoes of these species would find their way into town. Subsequent light-trap catches confirmed the practicability of this decision.

Mr. Dorer is State director, Communicable Disease Center Activities, Public Health Service, and engineer in charge of the bureau of insect and rodent control, Virginia Department of Health, Norfolk, Va.

The drainage ditch running through part of the town was marked for treatment with oil insecticides by the town sergeant and was thus disposed of as an inspection problem.

The major part of eliminating the fairly heavy production of domestic mosquitoes would depend upon alert and systematic house-to-house inspections and cooperation of the townspeople, the surveyors decided. They concluded that a voluntary program using the older school children during their vacation period was feasible and promising.

A detailed plan of procedure, which placed all the responsibility for its execution on the citizens of Stony Creek, was accepted and put into operation July 1, following a brief training course in the field for both youngsters and grown-ups.

Approximately 20 school children participated in the work until September 30. The town was divided into numbered districts, and

A typical mosquito source found in Stony Creek and removed by the young inspectors in the mosquito control project.

two young inspectors were assigned to each district. Each week they were given a different district. The inspectors always requested permission from the occupant before they investigated a premise—and met with wholehearted cooperation.

The inspectors recorded on a report form the premises inspected, the number of temporary and permanent breeding places found, and the action taken or recommended. They submitted the reports to the committee in charge at the end of each week.

When mosquito larvae were found in temporary containers, such as cans, bottles, buckets, or pans, the inspectors took a sample to show to the tenant and got permission to empty the containers.

The permanent breeding places, such as rain barrels and pools, basements, and cisterns, which the inspectors could not remove themselves, were reported to the club supervisor of the program. These places, with the consent of the tenant, were sprayed when possible by the town sergeant with larvicide purchased with funds appropriated by the town council.

In a town without a municipal water supply, the rain barrels presented a control problem. Through elimination, screening, or treatment of the barrels, much improvement was shown during the summer.

Field records indicate that 1,057 temporary mosquito breeding places were found by the inspectors and were eliminated during the 3 months the plan was in operation. A light trap was set up and serviced by a different pair of inspectors each week. Nightly catches were forwarded weekly to the Norfolk office of the bureau of insect and rodent control for identification and listing. Analysis of these trap records indicates that on no night during the period the program was in operation were there sufficient mosquitoes to cause annoyance.

As may happen in such a volunteer program, responsibility for achievement fell upon a few. Fortunately, enthusiastic leadership carried the program through its trial period. It received a fair test, and its success was indicated by the generally favorable reaction of the public. Various persons expressed approval, but the almost universal cooperation of the townspeople was, perhaps, the best evidence that the commu-

nity regarded the project favorably. Mayor Philip Freeman wrote on October 17: "I personally feel that it was very successful . . . for the first time in several years, it was possible to play croquet in my yard during the evening without being eaten alive by mosquitoes."

Probably, the program will not be continued in its original volunteer form; but it seems to have served more than one definite purpose. The people of Stony Creek have been made "mosquito conscious." They will no longer take these insects for granted under the mistaken impression that nothing can be done about them. Any improvement in living conditions is welcomed by the people affected, and they are usually willing to make a reasonable contribution of money or effort to insure continuance. Firsthand familiarity with the mosquito and its habits may develop into a demand for permanent control.

The use of school children in such a project has several advantages. Continual efforts are being made to introduce subject matter of this kind into classrooms because of the educational value to children at this formative age when they readily absorb and retain information of future value to them. There is further advantage in having them acquire practical knowledge from actual experience that is half play. Further, such teen-age activities acquaint the youngsters with their future civic responsibilities and should help to make them better citizens. It, also, was noted that several school children living in the surrounding rural area participated in the preliminary training course and took back to the farms some knowledge concerning control of mosquito breeding.

Finally, there is the great mutual benefit to be derived from a closer association between the health department and the people it was created to serve. A health department and its bureaus are not austere and unapproachable organizations that can be called on only in an emergency. Anything that tends to break down such a barrier is of benefit to those on either side. The activity reported here has opened friendly relations, and it is believed that, because of this experience with mosquito control, the townspeople are much more ready and willing to seek advice and cooperation in connection with other problems.

A Statistical Record System in a Local Health Department

By BEATRICE PEARSON, Ph.B.

A director of health constantly wants two kinds of statistical information: first, data which will acquaint him with the health needs of the community; and second, figures showing the extent to which the divisions of the health department meet local requirements for service.

Such information can be obtained by analyzing birth and death certificates, reports of communicable disease cases, and reports of the activities of the health department.

The problem, then, is one of finding a technique for handling available source materials so as to provide the most satisfactory statistical reports.

The Louisville and Jefferson County (Ky.) Board of Health introduced a new reporting method January 1, 1948, while Dr. John J. Phair was director of health. Although the basic procedures are established, the details are still changing and expanding to meet the needs of a growing program. It is thought, nevertheless, that the Louisville experience with the new system will be of value to others engaged in the administration of health programs.

Background

The Board of Health of Louisville and Jefferson County has jurisdiction over the county tuberculosis sanatorium, the city hospital, and the department of public health. The depart-

Mrs. Pearson is the statistician for the Louisville and Jefferson County Board of Health, Louisville, Ky.

ment of public health serves the community with the usual activities of a health department, including venereal disease clinics, well-child and maternal health clinics, school health services, a general program of public health nursing services, and sanitation, milk, and meat control services. Medical and nursing services are administered through six districts, three having health centers. Well-child clinics are located in 33 other sections of the city and county. A mobile unit covers less accessible rural areas, and a dental trailer serves the towns and rural communities. Preparation of vital statistics is also the responsibility of the department of public health.

Prior to January 1, 1948, all activities of the department of public health were reported in terms of the activities report code adopted in 1936 by the Public Health Service, the Children's Bureau, and the State and Territorial Health Officers (1).

When the activities report code was adopted, many health departments kept few, if any, records. Public health personnel in small communities remembered the history of each case. To convince them of the necessity of maintaining records was difficult. This was especially true of statistical records.

The activities report proved valuable in overcoming this attitude, and it played an important role in training public health workers to maintain and use statistical data. But, as public health activities were centralized in health departments, with a broad concept of public responsibility, serious weaknesses were seen:

1. The activities report gave only a frag-

mentary idea of the total program of the health department. Since pieces overlapped in some places, and gaps appeared in others, it was impossible to put together a comprehensive picture of the whole.

2. The work of a single division was inadequately summarized. Child health service, for example, was divided into service to infants and service to preschool children. Each of these services was again divided into medical and nursing service. The number of children served was not known, nor was there an accounting of the work actually done for the children in the well-child clinics. There were no correlations—no analysis was made of the relation between any two sets of data (2).

3. The code was too rigid. There was no effective way of working into the code changes in the program or additions to the services offered. As a result, many of the department's activities were incompletely reported.

4. There was no possibility of avoiding errors, or of finding them. Each staff member—doctor, nurse, or sanitary inspector—turned in a daily report in code. The daily reports were entered on monthly sheets and totals for each worker were compiled for the month. These totals were then carried forward to a "district summary sheet," and totaled for the district. District totals were carried forward to a "department summary sheet," and totals compiled for the entire department. Because the entries were in code, the original daily reports could not be checked for accuracy. Errors in copying totals did not become apparent because, again, these were in code. So there were no internal checks, and no cross-checking of totals.

5. Special studies, desired from time to time, were outside the framework of the activities report, and could be made only with the application of much time and labor.

The Louisville Card System

The activities report code was discarded in Louisville. A new code was introduced for use on a standard mechanical tabulating card. Each card represents one encounter between an individual and a health department representative. The card carries important facts about the person. It also shows all services received at each

clinic visit, home visit from a public health nurse, or sanitary inspection. The cards include all information formerly obtained from the activities report, and, in addition, a quantity of other data is readily procurable (3).

By using the mechanical tabulating card, it is possible to ascertain the total number of individuals served by the department for any time period; to learn their age, sex, and race, as well as place of residence. Any desired details about the work can be obtained, with special studies whenever necessary. Routine monthly reports include attendance at each type of clinic, showing the reason for the visit, and a count of the services received (physical examinations, immunizations, blood tests). Since each card contains information on every service received, the number of each kind of service shown on the monthly report is the actual count of services.

Information for special reports is available. There were, for example, more than 40 centers in Louisville and Jefferson County where child health conferences were held, some semiweekly, some monthly. After studying attendance at each center, using total attendance tables on infants, preschool and school-age children, and the number of new cases in each category, it was decided to decrease the centers to 35, to reduce the frequency of sessions at some, and to institute an appointment system to reduce the number of repeat visits by older children. Data for this study were easily obtainable: a code number for each center, as well as the necessary information on the children, is punched into every card representing a visit to a child health conference.

A tabulation made of nursing visits to new prenatal patients showing census tracts where the patients lived is another illustration of a special study. The study was used to determine where a new prenatal clinic would be of most value.

To obtain an accurate record of the incidence of disease, it has been the custom to count every attack as a new case. At a staff meeting, it was suggested that the high incidence of gonorrhea might be due not so much to an increase of infection as to a repetition of infection among a comparatively small group of people. To discover the truth, the statistical department suggested that the venereal disease clinics count as "new re-infections" any newly diagnosed cases pre-

viously reported as infected. A new code number was added to include a count of such cases with the result that monthly reports show not only the "new re-infections" of gonorrhea but also the occasional "new re-infection" of syphilis.

As the work of the divisions expands, the codes used are changed, and additions are made. The system's flexibility was illustrated when a new series of preventive antigens was introduced in the well-child clinics. When the change was made, the tabulating card code for immunizations was completely revised without disturbing the nurses or clerks. All cards are coded in the statistical office.

Mechanical tabulating cards are used for recording vital statistics. Resident and nonresident births and deaths are recorded on tabulating cards. From the cards reports of death causes can be made by age, sex, and race, and by residence. Births can be shown by age, race and sex, and residence of mother. Infant death rates in the city can be computed by census tract, and the causes of infant deaths can be shown in detail. Other studies can be made as desired. The new International Statistical Classification of Diseases, Injuries, and Causes of Death was adopted in 1950 by the Department of Public Health in Louisville and Jefferson County. Each death was coded, then, according to both the old and new classifications. Tables were presented according to both, for comparison with previous years as well as with future years.

Preparation of Source Material

To show best how results were obtained by the department of public health in Louisville and Jefferson County, it might be well to describe the steps taken in the gathering and tabulating of source material. Too many statistical studies and reports have been invalidated by carelessness in treating the original data. In order to insure the closest homogeneity of material, careful definitions of terms were established before the new method was instituted. Wherever possible, the definitions of the activities report code were retained, but they were clarified. New terms were introduced after definitions were agreed upon by the statistician and

doctors and nurses, or by the statistician and sanitary engineer. Once established, the definitions are adhered to and have universal application. As borderline cases occur, the defined terms may be expanded to include the new problem.

New staff nurses undergoing orientation visit the statistical department for instruction on the work under way. All staff members concerned with the records are encouraged to discuss the clarification of definitions with the statistical department. Every effort is made to keep source material accurate and uniform.

Home visits of public health nurses and field visits of sanitary and milk inspectors are recorded in the field directly on the tabulating card. Clinic visits are recorded on the "daily register and service analysis sheets" of the clinic. For each visit shown on the daily register sheet, a card is punched, similar to that used for the home nursing visit.

The card carried in the field by the nurse is precoded so that she has only to check an item beside the code. When a patient visits a clinic, his name, age, sex, and race are recorded on the daily register sheet. The clinic clerk locates his name in the master index card file, where, if he is a former case, a card is kept with his case number at the top. This number is entered on the register sheet. At the end of the day, the clerk numbers the new cases and prepares an index card on each for the master file. The clerk reviews the medical record of each patient, entering on the register sheet the services rendered the patient, such as X-rays, blood tests. Daily register sheets are prepared in duplicate; the original is sent to the statistical office; and the second copy remains in the clinic where it becomes an important source record.

Statistical Procedures

When the field visit cards and clinic registers are received in the statistical office, receipt is recorded on a check sheet. Then they go to the code clerk who checks for obvious discrepancies. Birth dates in the well-child clinics are given special attention so that the categories "infant," "preschool," and "school-age" will be correctly marked. The code clerk then codes all items not precoded. After the sheets have

been coded, they go to another staff member who checks for coding errors.

Field visit cards and clinic register sheets next go to a key-punch operator where a card is punched for each visit recorded on the register sheet. When the cards are completed, they go to the verifier who repeats the card punching as a check on the first operator.

Care in securing the accuracy of the original data is emphasized. The foundation of this accuracy lies in the reports prepared by nurses, sanitary inspectors, and clerks. The value of the final reports rests on the accuracy of the original material. Every effort is made by the statistical department to guarantee that the information will be tabulated as received.

Procedures for Sanitation Reports

The reports of the sanitation division are treated somewhat differently from those of the nursing division, although the underlying method is the same. Because of the complexity of the activities of sanitary and milk inspectors, it was impossible to devise a precoded card, or to have the coding done in the statistical office.

The sanitation code was set up in four parts: A. Type of premise, B. Origin of inspection, C. Problem to be investigated, and D. Action taken. The card has a space for each of the four code sections, and every field visit must be coded for all four. The inspector codes his own card, attaching it to his report. After reviewing the report, his supervisor sends it to the sanitation division's code clerk, who works in close cooperation with the statistical department. Her task is to check the code against the inspection sheet for correctness and consistency. For example, if a visit is coded as an "official call" in "B," it cannot be coded as "general inspection" in "C."

When the cards have been received in the statistical office, their receipt is recorded; they are key-punched and verified. Because only a few columns are necessary to record a sanitation or milk visit, the card has been set up as a "tumble card," and can be used again.

Preparation of Reports

For the monthly reports, all cards are run through a card-counting machine which sorts

them into pockets, according to the holes in the column on which the sort is made, and counts the number of cards in each pocket. After the first sort, each group of cards can be re-sorted on another column, and again re-sorted, so that a detailed correlation table can be obtained if desired.

Types of correlation tables are illustrated in tables 1 and 2. All data for table 1 were obtained by sorting the same cards according to different categories. In table 2 will be seen one of the many counts obtainable from the cards—in this instance, a correlation of sanitation services from the sanitation cards will provide valuable information to the administrators of a sanitation division in a health department. For sample correlation tables, as in table 1, the totals must be counted two ways: to obtain clinic visits by classification the cards are first sorted by "type of visit," and then each group is sorted by "classification." The figures obtained in this sort must add to the figures obtained when all of the cards are re-sorted by "classification." If a number has been put in the wrong cell, the error will be found, where merely checking the arithmetic cross totals would not have revealed it.

By placing all work on mechanical tabulating cards, each one representing one visit—to a home, to a clinic, or as an inspection—the department of public health can obtain from the first card sort totals unobtainable from the activities report. From these totals a summary of the work of each division is made as soon as the reports for a given month have been received and processed. By sorting the home visit and clinic cards by case number, it is possible to know how many individuals have been served by the health department.

Upon completion of the summaries, any information desired can be obtained by re-sorting the cards. The fact that a patient is new to a clinic, for example, is punched into the card, and this punch will always count as one new patient whether the cards are sorted by classification, by separate clinics, by X-ray services, or for any other category. Since a clinic service, such as urinalysis, is punched into the card representing that clinic visit, the total number of such services counted on the card-counting sorter must be the actual number reported by the clinic.

The number of individuals given any particular service, such as field visits for prenatal care, can be obtained by counting the "new" and "first this year" visits. When the cards have been sorted by case number, the number of cards bearing one case number represents the number of times that case was served by the department of public health. Similarly, to get the number of premises served by the sanitary inspectors, the number of "applications" and "first inspections" can be counted. By relating this number to the total inspections made, the average num-

ber of inspections per premise can be obtained. This can be done for total premises, or only for premises of a certain type, such as restaurants or nursing homes.

As the work of the health department expands, new code numbers for new services are added to the key-punch code.

In the sanitation division, "type of premise" is coded in 2 digits, the first representing the broad classification into which a premise fits. For example, all numbers beginning with "1" represent premises on which food is served.

Alcohol Studies and Rehabilitation In Virginia

By KENNETH F. LEE, M.A.

Encouraging evidence that a large percentage of chronic alcoholics can be successfully treated is found in the Virginia State Department of Health program for the study, treatment, and rehabilitation of alcohol addicts.

A recent evaluation of 816 treated patients showed that more than half had been helped to attain sobriety; about one-fourth showed marked improvement; and less than one-fourth showed no improvement.

The State program was established in 1948 by legislative action of the General Assembly of Virginia to determine if State aid can help persons addicted to the excessive use of alcoholic beverages. The program was not set up with the intention of solving the entire problem of alcohol addiction in the State.

Virginia's program on alcoholism is the culmination of the efforts of a number of citizens of the State, aided and advised by nationally recognized authorities on the treatment of alcoholism. The enabling legislation is among the first to assign to a State public health authority the administration of an act to combat alcoholism.

A study of alcoholism within the State provided the basis for developing the program. A research group, the Virginia Advisory Legislative Council, was authorized by the Virginia General Assembly in 1947 to make the investi-

gation and report back to the assembly 60 days prior to the convening of the 1948 session.

Size of Problem

Admissions of alcoholics to penal institutions were surveyed by the research group during the 4 years July 1, 1943, to June 30, 1947. Of the 70,077 jail commitments in the 1944 fiscal year, 29,116 were attributed to alcohol. By the end of the fiscal year 1947, the total of all arrests had increased to 98,034, and the total arrests on account of alcohol were 52,820. Thus, arrests for inebriation increased 81.4 percent during this short period. During the same period, arrests for drunken driving increased 119.3 percent.

Another aspect of the study concerned the number of first admissions, from 1910 to 1946, to the four Virginia State mental hospitals. Inebriates made up 13.7 percent of all first admissions during this period.

The records of three private mental institutions which admitted alcoholics furnished information on the number admitted during a 10-year period, and the records of a fourth were available for a period of 5 years. The average number of first admissions of inebriates to the four private institutions was slightly more than 500 persons annually, the advisory council found.

An estimated number of 15,000 inebriates and 45,000 excessive or problem drinkers in the State was derived from studies made available by the Research Council on the Problems of Alcohol of the American Association for the

Mr. Lee is director of the division of alcohol studies and rehabilitation in the Virginia Department of Health, Richmond, Va.

Legislative Action

The resulting legislation, Senate Bill 304, created the division of alcohol studies and rehabilitation within the Virginia State Health Department. The new division was given the assignment of studying the problem of alcoholism, treating and rehabilitating alcoholics, and promoting a preventive and educational program.

Hospital and clinic facilities for alcoholics accepted for treatment have been established by the Medical College of Virginia within the college hospital, as authorized by the act.

Under the law the director of the division, subject to the approval of the State health commissioner, may set up other treatment facilities in the State, within limitations of the appropriation.

To finance the program, the assembly appropriated \$116,525 for the fiscal year 1950-51 and \$117,325 for the year 1951-52. As a supplement to the official grant, patients who are able must pay the actual cost of their hospital care and treatment. In the administration of the act, it has proved feasible to have the patient pay at least part of the cost if he cannot afford the entire expense.

In planning the program, the Virginia State Health Department, as directed by the act, has sought the help and advice of established agencies in the country. Among the advisory agencies have been the Connecticut Commission on Alcoholism and the Yale Plan Clinic, the alcohol clinic of the Peter Bent Brigham Hospital in Boston, Mass., and the Payne Whitney Clinic of the New York Hospital and the alcohol service of the Knickerbocker Hospital, both in New York City.

Organization

Two standing advisory committees have been designated to aid the division of alcohol studies and rehabilitation.

The medical advisory committee has nine physicians representing the specialties of neuropsychiatry, internal medicine, and pharma-

cology. Seven are from Virginia and two from outside the State. The tenth member of the committee is a sociologist. This committee meets on call by its chairman and has contributed much to the organization of the division's activities and treatment procedures.

On the general advisory committee are eight persons representing the fields of education, religion, social service, private business, and organizations particularly interested in the social problems of alcoholics.

The staff of the division has a full-time administrative director who is responsible for the operation of the program, a medical director, and three physicians who are employed on a part-time basis. In addition, there are two psychiatric social workers and a clerical staff of five. The services of a clinical psychologist are used when psychological studies are needed.

Treatment

An out-patient clinic was established October 16, 1948, at the medical college hospital, and the in-patient facilities opened April 12, 1949.

At the end of January 1952, a total of 1,048 patients had been accepted for treatment—171 were initially accepted on an out-patient basis; 877 began treatment in the hospital.

Of the 1,048 patients, 138 were women and 910 were men. They have come from 64 of Virginia's counties and 21 of its towns and cities. Most of the patients have been between the ages of 36 and 40. The second largest group has been between the ages of 31 and 35. Only 17 patients have been less than 25 years old.

Admission

Eligibility for treatment is suggested by the act. Any citizen of the State who has become unable to care for himself through the excessive use of alcoholic beverages, or who is a burden to the public, may voluntarily request admission to the treatment facilities.

No patient is accepted for treatment against his will. But he may be referred by relatives, friends, ministers, physicians, social agencies, the courts, members of Alcoholics Anonymous, or by employers.

The limited facilities make it impossible to

accept all persons who apply. However, an effort has been made to select patients who represent various alcoholic problems with respect to age, sex, race, occupation, marital status, family background, and drinking patterns.

Unless the patient is in an acute alcoholic state at the time of admission or is in need of special diagnostic studies or treatment requiring hospitalization, his course of treatment begins in the clinic with an application interview.

A member of the staff tells the patient the general purpose of the clinic and orients him in the regime of treatment.

He is told that the clinic does not expect to give him a treatment lasting a few days or weeks. He learns that successful rehabilitation requires that he adhere to a prescribed, long-range treatment program administered by physicians, psychiatrists, social workers, and psychologists.

All treatment is prescribed and supervised by the medical director or by a staff physician assigned to the patient.

Special Services

All patients accepted for treatment are given a complete medical examination, and each of them undergoes an examination by a psychiatrist. A social history is taken and a psychological test is made if the physician in charge believes they are advisable.

Occasionally the physical examination will reveal a physical ailment that is influencing the patient's desire to drink—a condition that must be treated if the patient is to overcome his drinking problem.

Psychiatric guidance is an important part of the treatment. The patient's work with the psychiatrist, which often begins in the hospital, continues during visits to the out-patient clinic. During the sessions, the patient can discuss his difficulties with someone who does not condemn him, and who can often help him gain insight into his problems and guide him into better management of his life.

The social history, gathered by a medical social worker, provides information the staff members may use in understanding and helping the patient with any problems he may have in his family, social relationships, or employment.

It has often been necessary to work with a patient's husband or wife, or other relatives, and the patient's employer to learn more about his condition and to help members of the family as well as the employer to accept some of the patient's limitations.

Staff members hold frequent conferences to consider the patients' applications, records, and progress during treatment, and to develop appropriate treatment procedures. Shown are the medical director, psychiatric social workers, administrator, and staff secretary.

Psychological tests provide information about the patient's intellectual capacity and personality that is valuable in planning treatment and in determining whether he is suited to his present job.

After the testing is completed, a plan of treatment is developed for each patient, taking into consideration his own particular problems, capacities, and limitations.

Every patient who is physically and otherwise qualified is given an opportunity to volunteer to take the drug Antabuse as a part of his treatment plan. Antabuse is started while the patient is still in the hospital, and he continues its use daily while under supervision as an out-patient.

Follow-Up Treatment

A vitally important phase of the program is the follow-up treatment which all patients receive whether they begin treatment in the hospital or on an out-patient basis. This follow-up care covers a period of months and for some patients has continued for more than a year. Some patients have traveled more than 400 miles (round trip) to continue treatment.

Recently an out-patient service has been opened at Roanoke, Va., a city of about 100,000

population 165 miles southwest of Richmond. Patients making application at this clinic may be referred to the hospital facility at Richmond for treatment, or they may receive treatment on an out-patient basis at Roanoke, depending on their needs. This clinic reduces the distance a number of patients from this area of the State have had to travel to obtain the important follow-up treatment after leaving the hospital.

Employment Adjustment

Cooperation of employers has made possible many suitable work adjustments. During the past 3 years, the division has assisted more than 300 patients with their employment problems. Each staff member looks upon this aid as a part of his service to the patient. Sometimes the assistance consists of a talk with a previous employer. On other occasions, it has been necessary to make arrangements for employment in an entirely new field. Conferences with employers have led to other referrals for treatment by employers who wish to retain the services of a valuable man. An employer may seek aid for a skilled worker with many years of experience who is beginning to build up a serious record of absenteeism, particularly during the early part of the week. The return to useful, self-satisfying, remunerative employment is one of the worth-while services that may be provided the alcoholic.

Experimental Research

Concurrently with the treatment of alcoholic patients, a basic experimental research program has been inaugurated through the assistance of the professor of pharmacology and the research professor of biochemistry at the Medical College of Virginia. Two full-time research assistants are conducting the studies. Under study are (a) the effects of alcohol on cholesterol metabolism; (b) the effects of alcohol on carbohydrate and fat metabolism; (c) the possible detrimental effects of alcohol on the production of fatty livers; (d) basic experimental studies dealing with methods of treating acute alcoholic intoxication; and (e) the effects of environment and various commonly used drugs on the pharmacological action of alcohol.

These experimental studies sponsored by the division at the Medical College of Virginia are a part of the pioneer activities in this field now being conducted throughout the country.

Educational Activities

The preventive or educational aspect of the program is another important phase of the work. However, during the first several years the division has emphasized rehabilitation in order to obtain concrete evidence that alcoholism is a remedial condition. Although the

During daily group sessions, staff members explain technical aspects of alcoholism and the patients discuss some of the factors that led to their illness. The sessions include movies with appropriate discussion of the film before and after the movie.

limited facilities of the service have made an intensive educational program impractical, several educational activities have been developed. Members of the staff have spoken before numerous groups. Scientific articles have been printed and distributed. The March 1951 issue of the Virginia Health Bulletin, published by the Virginia State Health Department, was devoted to the activities of the division, and copies have been sent to other States, to all public schools in the State, to physicians, social workers, and others interested in the alcohol problem.

Possibly the most important activity is the annual symposium held by the division. Addresses presented by national authorities at the several sessions have been both beneficial and interesting to those concerned with the alcohol problem.

An appraisal of the results of treatment for the 3 years the division of alcohol studies and rehabilitation has been in operation is difficult. However, an evaluation of the therapeutic results for 816 patients made at the end of October 1951 showed that 57.2 percent have been helped to attain sobriety. Patients in a second group, 22.5 percent, have shown improvement in family relationships. They have lengthened their

periods of sobriety, and their employment situation is considerably improved. Persons in a third group, 20.3 percent, have, so far as can be determined, shown no improvement.

These results during the first 3 years of the division's activities appear to confirm the opinion of the State legislature that a large percentage of chronic alcoholics can receive benefit and make improvement in interrupting their drinking patterns through a program of rehabilitation.

Fears of Children

16 mm., sound, black and white, 30 min., 1951.
Audience: Teacher, parent, and child study groups.
Available: Loan—Inquire State health departments. Purchase—International Film Bureau, Inc., 6 N. Michigan Ave., Chicago 2, Ill.

Part of the series, "Emotions in Everyday Living," this film was prepared for the Oklahoma Department of Mental Health by the Mental Health Film Board and produced by Herbert Kirkow Productions. It has been approved by the National Institute of Mental Health, Public Health Service.

The film dramatizes some of the emotional problems common in childhood by telling the story of a 5-year old youngster, Paul, and the part that fear plays in his development. These fears—of the dark, of being alone, of new situations—prevent him from enjoying experiences

other boys enjoy. They create tension and anxiety between the boy and his parents, who have unintentionally accentuated the boy's problems by being both overprotective and unduly severe.

Paul's difficulties come to a head while he is exploring a cave with a friend. Paul reaches a state of panic. Alarmed, his mother talks this episode over with another mother and begins to understand how some of her own actions have contributed to her son's problems.

On another occasion, Paul is engulfed in a terrifying dream. His father, in questioning his own part in creating some of Paul's disturbances, learns to see the child's fears in a clearer light, and becomes better prepared to help the boy develop healthy mental patterns.

Farewell to Childhood

16 mm., sound, black and white, 23 min., 1951.
Audience: Appropriate teacher, parent, and child study groups.
Available: Loan—Inquire State health departments. Purchase—International Film Bureau, Inc., 6 N. Michigan Ave., Chicago 2, Ill.

This film is part of the series, "Emotions in Everyday Living." It was prepared for the North Carolina Board of Health by the Mental Health Film Board, and produced by the Julien Bryan International Film Foundation. It has been approved by the National Institute of Mental Health, Public Health Service.

"Farewell to Childhood" develops, in dramatic form, the story of Susan

Stewart, a normal teen-ager, and the difficulties she and her parents have in coping with the changes taking place in Susan's outlook and attitudes as she leaves childhood and enters adolescence. The girl longs for the independence and privileges of adulthood, but at the same time she fears them.

Her parents are bewildered by their daughter's behavior and her growing antagonism to their supervision. The inability of the parents and the girl to understand one another reach a climax when Mr. and Mrs. Stewart confront Susan as she returns late from a party one night and embarrass her and her escort with accusations and mistrust.

The girl withdraws from them, finding refuge in daydreams and in her admiration for her school counselor, which further distresses her parents. An approach to the solution of these difficulties is achieved when the counselor visits Susan's parents and helps develop in them a deeper understanding of their daughter's emotional "growing pains." A closer relationship between the girl and her parents results, making the thorny road easier for each of them.

Help Yourself to Health

Rural Health Factors

Rural health programs must go beyond efforts to attract physicians or to provide more and better medical care, the Seventh National Conference on Rural Health was told by John W. Cline, M.D., San Francisco, president of the American Medical Association. Farm people of America, who have always subscribed to the philosophy of individual independence, can develop a health program unequalled anywhere, he said.

"Americans always have believed that the individual must help himself to the limits of his own capacity," Dr. Cline stated. "By following this principle, and the broader concept of self-help through voluntary organizations of neighbors to solve community problems, we have grown strong as a Nation. This is the only method by which we can bring our rural health problem to adequate and satisfactory solution."

The AMA president urged the formation of community health councils, sparked by local community leaders. He outlined the farm health program:

(1) More aggressive programs to inform farm people how they can solve their own health problems. (2) Construction of more and better hospitals in rural areas which need them and are able to support them. (3) Establishment of adequate dental facilities. (4) Efforts to attract physicians to rural areas. (5) Encouragement of voluntary medical and hospital insurance programs. (6) Improved sanitation, as an important factor in the fight against communicable disease. (7) Immunization against such preventable diseases as smallpox, diphtheria, and typhoid. (8) Education of farm

people concerning proper dietary habits in order to build healthy bodies and to avoid nutritional diseases. (9) Programs to teach home nursing and first aid—and even better selection of clothing for farm folks.

Citizenship Responsibility

The chairman of AMA's Board of Trustees, Dwight H. Murray, M.D., of Napa, Calif., in a pre-conference session, urged the busy rural physician to undertake the added re-

At the call of the Council on Rural Health of the American Medical Association, some 700 leaders in medicine, agriculture, and education met in Denver, February 29 and March 1, to consider rural health problems. Under the general theme, "Help yourself to health," the conference heard reports from communities which have taken active steps to solve some of their pressing health problems. Public Health Reports presents here, in news-summary form, several of the case reports and general statements for which written texts were available.

sponsibility of leadership in the rural health movement. Dr. Murray pointed out that the interest of rural people in better health is increasing. "Steps are being taken to provide more adequate health facilities in an increasing number of rural communities. Community health councils are winning growing recognition for solving rural health problems. Progress is being made in attracting more doctors into rural practice. There is growing employment of health education specialists by land-grant extension services."

Rural Health Progress

Physicians are again locating in villages, according to the chairman of the AMA's Council on Rural Health, F. S. Crockett, M.D., Lafayette, Ind. "No community is too poor financially to provide itself with good medical care provided it is rich in faith and good works," he indicated.

At a preliminary meeting of State rural health committees and agricultural educators, Dr. Crockett had stressed the importance of self-help techniques and health education allied with sound medical practice in giving rural America an equal opportunity to share in curative and preventive medicine. He underlined the physician's role in the development of State and local health councils:

"Doctors have proceeded vigorously, promoting State and county activities. We doctors are of the opinion that the leaders in any community must assume responsibility for the local state of affairs."

If a health council is formed of representatives of all groups, its deliberations will reflect a broad section of public opinion and experience. "The entire health problem of rural America is in process of solution," Dr. Crockett added. "It is our privilege and duty as doctors and as health educators to encourage this program of local health councils."

Local Problems Solved By Cooperative Effort

MISSOURI. Missouri communities are solving their health problems through their own cooperative efforts, according to Chester G. Starr of Jefferson City, Mo., director of the rural health service of the

Missouri Farm Bureau Federation.

Studies of health problems within the State are stimulated by the Missouri Health Council on which 27 state-wide groups are represented, comprising nearly all organizations having a fundamental interest in health improvement. County councils have been set up in 60 localities.

Mr. Starr's report cited two studies as examples of what is being done to meet local conditions: a nutrition project in Miller County and a diabetes survey in Greene County.

Miller County is in the Ozarks. The local health council decided to conduct a representative survey in the county of what people were eating to determine if their diets were nourishing.

"The results of the survey are now being tabulated," according to Mr. Starr. "From this data, the health council is planning to push better nutrition. With actual figures to be quoted, with results pictured in maps, charts, and folders, with illustrated slides, the story of what is now true in the county will be taken to every home and better systems of nutrition suggested."

In Greene County, the health council was concerned about a possible high incidence of diabetes and embarked upon a survey of the prevalence of that disease. With almost 1,000 volunteers participating, 11,960 tests were made, of which 309 were positive. Each of the 309 persons was advised to consult a physician for a final diagnosis. All but 70 did so, and of those who did not, a number had moved, making a check-up impossible. "Contrary to general belief, many cases were found among babies, grade school children, and teen-age high school pupils. Many of these were unknown until tests disclosed their existence," according to Mr. Starr.

The purpose of the State council is to bring together for discussions and planning all health groups, to serve as a clearinghouse on health problems and programs, and to facilitate joint planning on State and local levels.

A state-wide survey is now under way in Missouri, involving medical, dental, and hospital care for individuals. "The State council hopes to

keep driving along from one project to another, not 'biting off' more than can be 'chewed'," Mr. Starr asserted in his report. "We are hoping that the examples of county work cited, plus many others that are being accomplished in other areas, will continue to stimulate the many folks 'at home' who should be interested in better health. Missouri is getting to be a better place in which to live and in which to rear a family."

Communities Initiate Own Health Projects

MICHIGAN. Small communities in Michigan are creating healthful conditions for themselves, according to John R. Rodger, M.D., of Bellaire, Mich., chairman of the Michigan State Medical Association's Committee on Rural Medical Service.

"A study of community health programs reveals that to succeed each project must be sparked by and led by at least one person who gives it the highest priority of his time available for community activities," Dr. Rodger emphasized. In reviewing achievements in Michigan, he pictured what the people of a community can accomplish if they unite to solve their own problems.

Two years ago, the residents of Livingston County, one of the few areas not having a separate health department, formed a community-wide health council. A study indicated the need for immunizations and better sanitation in the rural schools. A project was set up on township levels with civic, local government, and professional groups co-operating and physicians and nurses donating their time. For its outstanding community program, the county council received last year's State health council award.

In strictly rural Newaygo County, the people united to promote voluntary prepaid health insurance, assisted by the churches, newspapers, and public-spirited citizens.

When the question of health services arose in Kalkaska County, population 4,500, the suggestion was made that a health center might attract additional professional services. This

viewpoint was promoted. The community now plans the construction of an 8-bed hospital. While locally owned, it will be sponsored by a larger hospital in a nearby trading center. Next summer, a young physician will move to the county.

A community health council was organized in Emmett County to improve sanitation and recreation conditions. The community's garbage dump was a health hazard. An unsupervised playground on the waterfront was dangerous for children. For its achievements in garbage disposal, sanitation, mental health, and child guidance, among other problems, the council received the 1950 State council award for the outstanding community health program.

Farm, Labor, and Industry Join in Health Campaign

NORTH CAROLINA. Physicians of North Carolina, appalled by health statistics which placed their State in the lowest national ratings, promoted a citizenry movement in 1943 which brought results, reported Fred C. Hubbard, M.D., of North Wilkesboro. Representatives of agriculture, labor, and industry joined in campaigning for better health facilities and services.

The North Carolina Medical Care Commission, a permanent State agency, was created by the legislature in 1945. That same year, the Good Health Association was formed, composed of more than 200 representative leaders. In 1946, a rural health committee was appointed by the State medical society to cooperate with the association. In 1947 and 1949, the legislature appropriated approximately \$20,000,000 as the State's share of funds for the Hill-Burton hospital construction program over a 5-year period.

"The tangible results of the health program in North Carolina are everywhere in evidence in the form of new hospitals, new health department buildings, the new 4-year medical school, more doctors in rural areas, more rural health councils, more evidence of health conscious-

ness than ever before, more effective medical and health service and more prepaid health and hospital insurance," Dr. Hubbard said. Increased funds—State and Federal aid, and local monies—have resulted in the construction of 60 hospitals, 19 health centers, and 15 nursing homes, with 3,907 new hospital beds.

The intangible results, Dr. Hubbard believes, are even more important. "I should like to suggest in this connection the feeling that exists subconsciously in the minds of those people who are really interested in better health conditions, that here is a wholesome and unselfish, and an all-embracing program with unlimited possibilities for good to the community. There is a changed attitude toward health matters that brings them down to the individual level and stimulates a wholesome and democratic approach to these common problems."

Medical Scholarships Attract Rural Doctors

VIRGINIA. To solve the problem of getting rural physicians, Virginia now provides 50 medical scholarships of \$1,000 each, reported Edgar J. Fisher, Jr., of Richmond, Va., director of the Virginia Council on Health and Medical Care. The scholarship recipient, in return, pledges a year of rural practice for each year the scholarship is held. The State has also made available 74 nursing scholarships and is being asked to provide 12 graduate nursing and 10 dental scholarships. Dr. Fisher noted that the dentist shortage is even more acute than the physician shortage.

The council includes 53 state-wide groups, 100 local organizations, and many individuals in its membership. It has concerned itself with such special problems as aid to crippled children, internships for Negroes, preventive medicine, nutrition, and hospitalization of indigents.

Since its inception 6 years ago, prompted by demand of the State's citizenry, the health council has, in addition to the creation of scholarships, supported these movements:

(1) A hospital construction pro-

gram which has resulted in 1 medical service center, 18 new hospitals, and 9 health centers, with others in planning stages. (2) The transformation of many beds in State tuberculosis sanatoriums from pavilion to hospital type. (3) The establishment of 11 tumor clinics and a bureau of cancer control in the State health department. (4) The establishment of public health services, doubling the counties previously covered. (5) The improvement and expansion of State medical education. (6) The improvement of the care of the mentally ill.

To encourage physicians to locate in rural areas, the council urges small communities to provide hospitals. Also, it has set up a placement service for putting physicians in touch with communities seeking physicians.

Dr. Fisher explained the functioning of the health council's placement service. "We contact the juniors and seniors in our two medical schools each fall to acquaint them with our service. We also follow the interns from the two schools as they leave the State, encouraging them to return and offering the facilities of our placement service to them. We contact the interns who come to our teaching centers from outside the State. By doing this and by having more information on locations readily available, we find doctors are much more apt to settle in Virginia."

University Recognizes Rural Training Required

COLORADO. More rural "family doctors" for Colorado is the result of a general practice residency training program at the University of Colorado's School of Medicine, in the opinion of Charley J. Smyth, M.D., of Denver, the school's director of graduate and postgraduate medical education.

After completing their residency, more than half of the trainees have settled in the rural areas of Colorado. A candidate for the special program must be a graduate of an approved medical school and have completed one year's approved in-

ternship. A 2-year course is provided for the young physician wishing to practice in a large community or as a member of a group where he will not be performing major surgery. For the physician who needs training in certain aspects of surgery, and who will practice in a rural area or do solo practice in a large community, a 3-year course has been prepared.

Because of the clear realization that graduate training had directed its emphasis toward the specialist, thereby contributing to the impersonalization of medicine and the disappearance of the general physician, the residency training program was established at the university.

"It was recognized that the far-reaching advances in scientific medicine were the results of specialists and that we would always need thoroughly trained specialists," said Dr. Smyth. But, he added, "It was equally apparent that there is still a need for a general physician interested in bringing these diverse special skills and knowledge together for the patient's benefit. With that understanding, the undergraduate curriculum was changed in 1947 to broaden the education of the medical student so that he would see in practice a type of medicine based on understanding the multiple factors which bear on human health and disease."

—Dr. Thode's Experience—

"One day, the thought suddenly struck me—why do I want to be a pediatrician?" Today, Henry P. Thode, Jr., M.D., is a general practitioner in Fort Collins, Colo. Five years ago, in 1947, he applied for a general practice residency at the Colorado University Medical Center and was accepted. The program was set up as a rotating service—including medicine, surgery, obstetrics, gynecology. Dr. Thode felt he had been marking time and getting nowhere as a potential specialist. Conversations with older and experienced doctors confirmed his opinion that general practice is the basis of all medical practice.

After additional training in Denver and Pueblo, Dr. Thode went to

Fort Collins, a community in northern Colorado. It was the turning point of his life. "Here, at last, I saw, and learned, and participated in the general practice of medicine. To put it mildly, I had no conception of just what general practice consisted. The volume, variety, and level of medical care in our community never ceases to amaze me, even today. I say 'our' community advisedly; because today, I believe I am a member in good standing in this community. I am in practice with an older doctor and gentleman. He did not know me, or I him, and yet we are partners today, an association of which I am extremely proud and for which I am very grateful."

Fifty Medical Students Train for Local Practice

ILLINOIS. The problem of a decreasing supply of rural physicians in Illinois is being met by a cooperative "Education for Need" program, instituted by the Illinois Medical Society and the Illinois Agricultural Association, Harlan English, M.D., chairman of the Illinois Medical Society's Committee on Rural Medical Service, told the conference. In assessing health problems and health achievements for his State, he interpreted Illinois' physician-shortage problem as one of educating the right people for the right places. Because of a decreasing population, he explained, actually no greater numbers of doctors and nurses are needed.

"In our State, a farm boy with dirt on his shoes, sunburn on his face, and lots of common sense in his head, but without a Phi Beta Kappa key or rich uncle, has trouble getting into our medical schools," Dr. English stated. This difficulty he attributes to "intensive competition to enter medical schools and the very, very difficult administrative problems involved, that apparently could be resolved, not solved, by scholastic ratings."

Dr. English described the efforts of the Illinois Medical Society and the Illinois Agricultural Association to identify those counties in greatest

need of medical replacements. Medical school authorities were then approached, he said, with the suggestion that "we, as a Loan Fund Board comprised of three representatives of medicine and three from the Agricultural Association, would contract with students having minimal averages but who were native sons of these most needy counties that in return for loans of \$1,000 to \$5,000 the students would be educated and returned to practice in their home counties only. We have 25 such students now in the processes of medical education and will have 50 more in the next 5 years."

Also, administrators of small "down-state" hospitals were approached, Dr. English reported, about educating nurses from localities where the need was greatest, with the specific contract that the nurses return to their home counties to practice nursing. If they married, they were to contribute sufficient funds to the nursing school fund to educate another nurse, he said. This program has been so well received, according to Dr. English, that it has enabled the smaller hospitals without nurses' training schools "to get by," and to have more and more bedside care performed by nonprofessional personnel with only 60-70 hours' training.

Illinois is blessed with many bounties, not the least of which is a good educational system, commented Dr. English. Its mortality and morbidity figures have never been the highest in the Nation, giving evidence, in his opinion, that its citizens are reasonably well-informed on health matters and have available reasonably competent health and medical personnel. New hospital beds—1,214 in 18 different towns where the need of additional facilities was urgent—have been built, with Illinois citizens raising two-thirds of the cost of construction under the Hill-Burton program.

What has Illinois done about local health departments? Dr. English mentioned that 26 of its rural counties have established health departments after a referendum vote and that where personnel can be found to staff them, the work of these health units is satisfactory. "Basi-

cally, in our State," he said, "the local township clerk is the township health officer. Between the elected officials, the school administrators, and the members of each county medical society, most of the health problems of public character are discussed, the citizens advised, and a proper public action is taken. Some say this system is archaic, but in Illinois it seems to work as well as the most expensive systems so far devised."

Dr. English further summarized local health achievements in Illinois by noting that grade A milk ordinances have been passed in most towns over 5,000; a brucellosis eradication program was inaugurated last year; 98 counties have enacted, by local option, tax measures to be used, if necessary, for tuberculosis control. A recent count, he said, showed that 17 cities had fluoridated their water supplies, and evidence collected so far reveals that "this simple chemical mechanism will decrease dental caries to such an extent as to be worth far more than the approximately 20 cents per family per year which the program costs."

"Such in brief is how the citizens of Illinois have improved their health status," Dr. English concluded. "The greatest single cornerstone or foundation stone in this improvement progress has been based on local community and county activity. It seems to us in Illinois that good health like good corn starts growing from the roots up and not from the tassel down."

Doctors Face Challenge In Small-Town Areas

SOUTH DAKOTA. Kenneth Kaisch, M.D., of Philip, S. Dak., gave those attending the Seventh National Conference on Rural Health a few simple rules to help a small town get and hold a doctor.

1. To obtain a doctor: Provide adequate hospital facilities and personnel, office space for a doctor to rent, and the type of town in which a person would want to live.

2. To keep a doctor: Treat him

as a human being with the same mental outlook and physical stamina as any other human being; try working with him instead of against him.

Dr. Kalsch spoke with the authority of personal experience when he stated that some small towns have more difficulty in keeping a doctor than in getting one. Finding the lot of a young doctor in a big city like Detroit a grueling one—he took up practice there after graduating from the University of Michigan Medical School—he selected a South Dakota

town of 900 people where there was no doctor within 26 miles.

His choice was not ideal from a doctor's standpoint. The hospital was a converted old wooden house, with a single room as the only available office space. Rental housing was available and the school system was good; improvements were promised and some of them were achieved. But, since practicing in a small town, Dr. Kalsch has compared notes with other physicians serving small communities.

Among the difficulties encountered is gossip. Another deterrent to service in small communities is the feeling that the city physician is better trained, with the result that the small-town physician frequently is by-passed except for emergencies or ordinary ills. Small-town physicians are on call 24 hours a day.

"If the townspeople only would regard their doctor in the same light as themselves, many small town practitioners would not go to an early grave," Dr. Kalsch advised.

Cancer Nursing In the Basic Professional Nursing Curriculum

In response to requests from instructors, this publication was developed by a Cancer Nursing Content Production Committee made up of representatives of nursing education and nursing services. It was designed to provide an outline showing how cancer nursing training might be incorporated into the basic professional curriculum and to suggest content materials which would be useful in preparing students to give skilled nursing care and to know and understand the etiology, symptoms, diagnosis, and treatment of the disease and the rehabilitation of the patient. The outline suggests the problem solving approach, and may be expanded or limited as necessary to integrate it into the basic curriculum.

The monograph discusses the cancer problem, the place of and need for expansion of cancer nursing in the curriculum, the roles of teacher and student, and problem solving. The suggested outline for teaching covers the nature of cancer; prevention; detection and diagnosis; treatment and nursing care; rehabilitation, including the patient and the rehabilitation process, resources, and programs; and the concepts of cancer

control. Two illustrations of problem solving in teaching cancer nursing are given: (1) for breast cancer and (2) for cancer of the rectum and colon with a colostomy. A sample cancer survey form and a bibliography of 113 references are included.

Cancer Nursing in the Basic Professional Nursing Curriculum—Suggested Content and Methods by Cancer Nursing Content Production Committee. (Public Health Service Publication No. 147) 1951. 27 pages. 5 cents.

Mental Health Pamphlets And Reprints Available For Distribution, 1951

This is the third edition of the catalog of current mental health pamphlets, first published by the National Institute of Mental Health in 1949 to fill the need for a standard reference guide to mental health materials. The 1951 edition contains 300 new items which are classified under the following main headings: National Mental Health Program, Mental Health Information for Professional Personnel, Mental Health Guidance, Mental Health Problems, Mental Health Services, Study Programs and Group Activity. Each of these sections is broken down into appropriate subheadings.

The references are not annotated, although the price of each pamphlet,

when known, is given with the source of the material.

Catalog of Mental Health Pamphlets and Reprints Available for Distribution, 1951. Public Health Bibliography Series, No. 2 (Public Health Service Publication No. 19, third edition) 1951. 53 pages. 25 cents.

The Public Health Nurse In Your Community

Designed as a recruiting aid, this publication describes the activities of the public health nurse and outlines the organizations which employ nurses. Qualifications, needs for nurses, and opportunities in the field are also covered.

The Public Health Nurse in Your Community. (Public Health Service Publication No. 47) 1951. 13 pages; illustrated. 10 cents.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Nutrition for the Later Years of Life

By ANCEL KEYS, Ph.D.

"Nutrition for the later years of life" implies that older people have special nutritional problems simply because they are older. The suggestion is that dietary practices considered good for younger adults may not fit precisely the needs of older people. Actually, there is practically no evidence that age, by itself, produces nutritional problems which do not have their counterparts at all ages in adult life. However, the frequency of certain problems changes with age and there are some general trends which need attention from those who advise or care for elderly persons, as well as from the elderly person himself.

It is impossible to specify any particular age to which this discussion applies, or begins to apply. Physiological age and a mode of life cannot be predicted from age in years alone. A part of the "old age problem" in the United States is the result of an overemphasis on years as a measure of biological status.

We are concerned here with individuals who have definitely reached the period of a substantial decline in physical vigor and activity, who have established relatively rigid patterns of food habits, and whose life experience has allowed the accumulation of some of the infirmities we associate with old age. For the individual, this age may start at 40 years, or it may be postponed to 70 or more; commonly, it is reached in the sixties.

There is no specific nutritional problem in old age nor any specific dietary recipes for the pres-

ervation of vigor or the extension of life in the aged. Throughout history and in all parts of the world, special diets—foods to eat or not to eat, foods in particular combinations or sequences—have been offered to a wishful and gullible public for the prevention or "cure" of the changes in physical and mental capacity associated with growing old. When there is an abundance of food, as there is in the United States, the scope for the food faddists is unlimited.

Part of the problem of providing nutritional help for older persons consists in countering the claims of the food faddists, the purveyors of special nostrums offered for nutritional purposes, and the writers who find a ready sale for books and articles promising miracles from peculiar diets. The older person who observes deteriorative changes in himself is especially vulnerable; the greater the loss of the sense of well-being, the stronger is the urge to believe any promise of help. Some highly publicized diets and nutritional "treatments" may be harmful, but the majority are not really dangerous. The main objection to false propaganda about nutrition is that it interferes with the teaching and understanding of sound nutrition. The primary means of improving nutrition, even with the aged, must be education.

Decreased physical activity of the older person indicates that there must be a quantitative change in nutritional requirements, at least in calories. Changes in body size and in basal metabolism also point to decreased total food needs. Decreased food consumption is, as it should be, the rule. However, with decreased total food consumption, the pattern of the remaining diet may represent an unfortunate selection; therein lies one basis for malnutrition.

Dr. Keyes is director of the Laboratory of Physiological Hygiene of the University of Minnesota, and professor in the University's School of Public Health.

Malnutrition Among Aged Persons

It is frequently said that malnutrition is much more common among aged persons than in the rest of the population, but there is little real evidence on the subject. Surveys of food consumption purporting to show a high incidence of dietary inadequacy in older persons use arbitrary standards of nutritional "requirements" which may be excessive for the whole population and which make no concession to the fact that the older person represents a smaller and considerably less active metabolic machine.

Nevertheless, it is possible that the incidence of malnutrition is relatively high among older people. A large proportion of elderly people have chronic disorders or diseases; some of these tend to promote malnutrition, particularly by restricting the choice of foods. Missing teeth, faulty dentures, slow digestion, and diminished taste acuity contribute to change the choice of foods. Dysentery or other diseases may cause inefficient intestinal absorption which, in turn, may reduce the actual nutrient supply to the tissues.

While the foregoing factors may have great importance in some individuals, it is probable that more purely psychological and sociological factors are influential in inducing malnutrition in older persons. A reduction in calorie needs is usually accompanied by a reduction in food interest, particularly for food variety, so that many older persons incline to progressive simplification and monotony in their self-selected diets.

When elderly persons prepare their own meals, easy availability and ease of preparation may dominate food selection, with resulting neglect of nutritional quality. This is often true in the older person who lives alone. In many communities the most extreme cases of malnutrition are seen in two classes of people—alcoholics and elderly recluses—both of whom tend to great oversimplification of the diet.

Economic factors are also important in malnutrition among older persons. At the present time, a large proportion of aged persons in the United States have totally inadequate economic resources; their meager savings, fixed incomes, and pensions are insufficient to adjust to rising

food costs except through drastic curtailment of food expenditures. This usually means less of the "protective foods"—meats, dairy products, fresh vegetables, and fruits—with replacement by cheaper items such as bread, potatoes, and sweets. A similar pattern is often seen in boarding houses and homes for the aged, where the necessity of operating on a limited budget leads to a qualitative nutritional minimum.

The kinds of malnutrition found in older persons are those found at all ages of adulthood. The older person tends to follow the dietary pattern of the community rather than any special pattern of old age. For example, if the community dietary pattern is conducive to pellagra, then pellagra will be found frequently in the older members of that community. There is, however, an important qualification. The older person tends to follow the dietary pattern of the years when his own life habits were being formed. This in itself may account for more malnutrition in older people than in the rest of the community who profit more from the advance of nutritional knowledge. Grandmother did not grow up eating oranges and hence is not in the habit of eating citrus fruit; grandfather was not reared to eat what he may term "rabbit food" and so is not interested in salads and green vegetables.

Calorie Needs

The basal metabolic rate declines steadily with age. At equal body size (surface area), the decline is of the order of 3 to 5 percent per decade beyond the age of 50 years. Moreover, in old age the body size diminishes, both in weight and in height, so that the estimated decline in that portion of the individual's calorie needs which pertains to basal metabolism is about 5 percent for every 10 years.

In young adults, physical activity accounts for at least half of the total calorie needs, and in some individuals two-thirds or more of the total energy expenditure is due to physical activities. This energy expenditure is reduced progressively beyond the twenties, but a more striking diminution in physical activity occurs when real old age sets in. The aged person rarely engages in manual labor, for the good reason that he is seldom capable of it, and his various infirmities

incline him to a sedentary life. Unnecessary activity is avoided, and movements are deliberate. There are exceptions, of course, but the general rule is a great reduction in calorie needs as compared to those of young or even middle-aged adults.

Records of food consumption under controlled conditions provide detailed confirmation to what is generally known from ordinary observation. Body weight in elderly people is often maintained with intakes of 1,500 calories or less in women and 2,000 calories or less in men. These low intakes are not a cause for concern so long as body weight and nitrogen balance are maintained. Unless the person is already unduly thin, some small progressive weight and nitrogen loss is to be expected, because the aged person certainly does not maintain—and cannot have—the muscle mass of 40 years earlier. If the body weight at age 70 is the same as that at age 40, it is almost certain that there has been a large gain of fat.

Obesity

Calorie undernutrition, of course, can and does occur in old people, but in the United States the opposite form of malnutrition—obesity—is far more common and troublesome. Insistence that elderly people should continue to eat as they did when younger is one of the more dangerous implications of the publication of tables of calorie “requirements” which make no allowance for changed conditions in the later years of life.

Obesity is a double handicap to older people. First, an undue burden of sheer weight must be moved by muscles—including the heart muscle—that are becoming progressively weaker. Second, obesity is a health hazard of great consequence, because the continuance of vigor and of life itself in the elderly is a contest against the progress of the so-called degenerative diseases, particularly diseases of the cardiovascular system and diabetes, and obesity very clearly seems to promote these. Cancer and the other neoplastic diseases are likewise special enemies of the aged, but a direct implication of obesity in them has not been proved. In animals, however, chronic undernutrition exerts a protective action against cancer.

Dietary Needs

Nutritional needs of older people, then, are not different in kind but only in amount; proteins, fats, carbohydrates, vitamins, minerals, and salts, all have their place in the diet.

Proteins

It is currently customary to insist on a relatively high protein intake for old people. Actually, there is no evidence that the old man's protein needs are higher than those of the young man; indeed, it is possible that the older person may actually “require” slightly less protein than he did earlier in life. This would follow, perhaps, from realization that in old age progressive muscular atrophy is yielding some endogenous nitrogen which might serve other purposes in the body; the amount is trifling, however, and seldom could exceed the equivalent of 5 pounds of lean meat in a year.

The recommendation of a generous protein intake is defensible on the grounds that one should combat a common tendency of old people to choose a very high carbohydrate diet—grandmother's “tea and toast” regimen—and that high-fat diets are specifically objectionable for the aged. General rules may be inapplicable to some individuals, but it appears that a daily allowance of 1 gm. of protein per kilogram of body weight is at least as adequate for the old as it is for the young. Furthermore, it is wise to insist that several different food sources make substantial contributions to the total protein intake. The rule of variety in the diet is useful here, since it helps to assure adequacy of other nutrients.

Fats

Strictly nutritional evidence points to a small need for dietary fats as such. In human diets, fats are important as a source of calories, as a vehicle or aid for absorption of fat-soluble vitamins, and for their effects on flavor and consistency of foods. Commonly, American diets seem to provide 30 to 40 percent of their calories in the form of extractable fats (and oils), but this percentage could be lowered substantially without any necessary nutritional harm. Since fats are reported to cause “indi-

gestion" in the elderly, and there are other reasons for recommending a low-fat diet in this age group, the limitation of fat intake to 15 to 25 percent of total calories seems reasonable.

Carbohydrates

It would seem enough to advise limitation on the most highly refined carbohydrate foods—sugar and white flour—in favor of more natural mixtures of nutrients. These impose less violent loads on the sugar-regulating machinery of the body and are less apt to produce digestive disturbances in persons who suffer from sluggish digestive processes.

Vitamins

The vitamin needs of older persons are, if anything, less well known than those for younger persons. There is a very large margin of uncertainty as to what amounts of the several vitamins are definitely required and what additional amounts are useful in any way. Since older people generally tend to show greater variability at the same age than do younger people, it is reasonable to suspect that they have large individual variability of vitamin needs.

In recent years there have been some attempts to show that older people have, on the average, relatively high vitamin requirements. Although these studies have yielded much valuable information, they have signally failed to establish the general thesis of elevated vitamin needs in the aged. On the other hand, there is no evidence of diminished needs with advancing age except, perhaps, for those vitamins which are required in proportion to the total metabolism or to the total carbohydrate metabolism. Thiamine seems to belong in this class, and perhaps riboflavin and niacin may be included because they participate in carbohydrate metabolism. But the safest course is to provide all of the vitamins in amounts that would be considered appropriate for younger people.

Minerals

Many of the foregoing remarks about vitamins could be applied with small change to the mineral needs of older people.

Attention is usually concentrated on iron and calcium for the aged. A mild anemia, which

may respond to iron therapy, is common in older people. In these cases it is probable that low iron intake is responsible rather than an elevated need for minerals in elderly persons. A diet with a good provision of lean meat, liver, eggs, whole wheat, leafy green vegetables, and dried fruits—raisins, peaches, apricots—will supply ample iron as well as the trace elements (copper, cobalt) which are necessary for blood building.

The calcium problem is not quite so simple. Progressive demineralization of the bones is a characteristic of old age, or at least of extreme old age. Whether this can be prevented by extra calcium in the diet is highly questionable. In some cases of rather similar but more definite bone disorders, such as hunger osteopathy, extra calcium seems to be far less beneficial than prolonged treatment with vitamin D. But there is no evidence that vitamin D is useful in retarding or preventing demineralization in the aged. Conclusions based on the measurement of calcium excretion in older people are likewise questionable in the absence of data to show that extra calcium influences in any way the long-range calcium balance in old age. There is much evidence to show that experiments of a few days or weeks may be totally misleading about calcium requirements.

From such negative arguments it might be suggested that the conservative answer would be to insist on superabundant calcium intakes in case they might be useful. However, calcium deposition in tissues other than bones is definitely a real problem in old age. The possibility of promoting such deposits is not to be accepted lightly. Fortunately, however, the body's capacity to regulate its own calcium balance is such that the provision of a good ordinary intake—say 1 gm. daily—seems unlikely to promote either calcium depletion or deposition.

Salts

The dietary supply of salt or, more specifically, of sodium, raises special questions because of the high incidence of hypertension and cardiac failure in the aged. In some hypertensive patients, rigid restriction of sodium intake is beneficial. High salt intakes are deleterious to the patient in or on the verge of cardiac failure. What then, should be the ad-

vice to the elderly person who does not have hypertension or exhibit indications of approaching cardiac failure?

Apparently moderate restriction of salt is of no benefit in the treatment or prevention of hypertension. Nor is there any evidence that moderate salt restriction will delay or prevent the cardiac failure which may develop on an ordinary salt intake. The very low sodium intakes prescribed in the treatment of hypertensive patients cannot be advocated except in real medical emergency; they impose an almost intolerable mode of life on the individual and pose a very serious problem in maintaining good nutrition.

The conclusion is that the elderly person would be well advised to avoid high sodium or high salt intakes but not to attempt serious restriction of either one. Unless the weather is excessively hot, a daily intake of 3 to 5 gm. of sodium chloride would be ample and would satisfy all ordinary tastes after a few days or weeks. In very hot weather and under other conditions which produce excessive perspiration, the salt intake should be increased to correspond with the fluid intake. Salt tablets are rarely desirable.

The Atherosclerosis Problem

Atherosclerosis is unquestionably one of the most, or perhaps the most, serious health problem of old age. While this is a slowly developing condition, probably beginning far earlier than when old age is actually at hand, any possible influence of nutrition in old age upon this disease must receive close attention.

The incidence of atherosclerosis is much increased in obese persons, although it may occur in persons who have always been thin. Also, the development of atherosclerosis tends to be related to the level of cholesterol in the blood serum, although, again, it may occur in persons who have relatively low cholesterol values. The diet should be such as to prevent obesity—or to correct it if present—and, if possible, to keep the blood cholesterol level at a relatively low level.

Arguments that the amount of cholesterol in the diet may be reflected in the blood level are not supported by more critical studies of man.

Only at extremely high intakes—far above the cholesterol content of all ordinary diets—is there reason to believe that the dietary cholesterol has any influence on the blood level. But evidence is steadily accumulating that the fat intake in the diet has an important effect. The blood-serum cholesterol level rises on high-fat diets and falls on low-fat diets. Moreover, there seems to be no discernible difference between animal and vegetable fats in this respect.

Excretion and Dietary Bulk

The incessant barrage of advertising of laxatives, cathartics, and bulk-formers is probably more responsible for the wide use of such materials by older people than any natural need. Many older people are, or think they are, troubled with constipation. A common tendency in old age to use diets which have small residues, coupled with the fact of smaller total food intakes, naturally leads to progressively smaller and less frequent stools. It is by no means clear that this is necessarily undesirable physiologically, but it often causes concern and resort to laxatives which may, in turn, disturb the orderly rhythm of excretion.

A more reasonable approach to the control of bowel regularity is to include in the diet foods which provide an appreciable residue for excretion—root and leaf vegetables, fruits, and whole grain or incompletely extracted cereals. Whole corn kernels are not recommended because they may be irritating. The specific addition of bran or ground cellulose is rarely desirable, in view of their irritating effect on the intestines. The constant use of mineral oil is objectionable for several reasons, including possible interference with the absorption of fat-soluble vitamins. Finally, a good deal of constipation would be “cured” if patients could be convinced that failure to have a bowel movement every day is not necessarily cause for alarm.

Longevity

It might be presumed that a “good” diet should be, among other things, “good” for the achievement of maximum longevity. But this raises the question whether the best diet for

extending the years of life is also best in all other regards—maintenance of vigor, resistance to infection, wound healing, sheer enjoyment of life, and so on. In those animal species which have been studied, chronic underfeeding seems to be the surest way of achieving long life and, within limits, the life span is proportional to the degree of underfeeding, particularly when underfeeding is applied during the period of growth. The attainment in man of maximum longevity by such means is hardly desirable or practicable. Moreover, there is no evidence that underfeeding in old age would have any such effect.

Nutritional Education

In old age, as at other ages, education is the most reliable way of assuring good nutrition. For older people who care for themselves, nutritional education cannot be stressed too much. Their nutritional knowledge lags far behind that of their younger contemporaries. Emphasis should be placed on practical matters, but the reasons behind the nutritional advice should be explained. The following may serve as reminders of important points to be covered.

1. A good diet is just as important in old age as in youth.
2. Overeating is more dangerous for the old than for the young.
3. Older people should be sparing in the use

of all fats and oils and should avoid cooking in fat.

4. The simplest way to assure adequacy of proteins, vitamins, and minerals is to use a varied diet made up of natural foods with a minimum of processing.

5. Cooking in large quantities of water is certain to result in losses of vitamins and minerals.

6. Liberal use of leafy and root vegetables, fruits, and coarse cereals will help control constipation. Failure to have a regular bowel movement every day is not constipation.

7. Bread enriched with milk solids and vitamins is desirable.

8. There should be an abundant fluid intake, and this may include moderate amounts of coffee, tea, and alcoholic beverages. The latter are best taken with, or immediately before, meals.

9. Meat, fish, or eggs every day should be the rule.

10. Special food concentrates and nostrums are seldom necessary. Peculiar and fancy diets should be avoided.

11. Moderate limitation in the use of table or cooking salt is wise.

12. A physician should be consulted if there are pronounced changes in weight or energy, or peculiarities of the skin, mucous membranes, or tongue. A periodic physical examination is advisable.

13. Food should be a source of pleasure and of health; the proper use of nutritional knowledge will help to assure that this is so.

Health Program in Ethiopian Road Building Project

The Public Health Service recently assigned a medical officer and a sanitary engineer to safeguard the health of 50 American engineers, their families, and 1,000 native laborers building a 700-mile highway in Addis Ababa.

At the request of the Government of Ethiopia, the highway is being constructed by the Bureau of Public Roads, United States Department of Commerce. World Bank funds are being used for the project.

The medical officer will operate a mobile medical clinic. He will be responsible for contacts with the National Ministry of Health and local medical personnel and hospitals, concerning his work and the care of patients.

The sanitary engineer will be in charge of planning and administering all sanitation measures for disease control, including water supply, food service, malaria control, and general sanitation problems.

Temperature Effect on the Colloidal Mastic Test

By GEORGE R. CANNEFAX, B.S., and C. W. TOW, B.S.

The colloidal mastic test is widely used as one of the laboratory diagnostic aids in the management of central nervous system syphilis. The procedure is highly sensitive to slight changes in laboratory technique, and it has been thought that the temperature at which the test is performed may influence the results.

The sensitivity of the colloidal mastic test is affected by several factors, such as electrolyte concentration, type of electrolyte, and size of the colloidal particles. When these factors are adequately controlled, reasonably reproducible results are obtained. However, there are times when the sensitivity of the test varies from the usual or expected level, indicating that there are other factors concerned. Since temperature changes affect activities of colloids, and no reference could be found in the literature, this study was initiated to determine the effect of various temperatures on the sensitivity of the colloidal mastic test.

Materials and Methods

Three reagents were prepared in sufficient quantities for 270 tests: a 10-percent solution of gum mastic in absolute ethyl alcohol; a 1.25-percent sodium chloride solution; and a 5-percent solution of potassium carbonate in freshly distilled water. Cutting's (1) modification of the colloidal mastic test was used, and the sensitivity adjusted with optimally alkalized salt solution. Dehydrated stable control serum (2)

Mr. Cannefax is laboratory director and Mr. Tow is a medical technician at the Public Health Service Medical Center, Hot Springs, Ark.

was used as the constant source of specimen material in the test performance.

Sufficient dehydrated stable control serum was reconstituted to the proper volume for use as a control for colloidal mastic tests. The control was apportioned in stoppered test tubes in amounts sufficient for one day's testing and frozen until needed. For each day's tests, one tube was thawed and 100 ml. of a 1:4 dilution was made with optimally alkalized 1.25-percent salt solution. Ten serial dilutions, using alkalized 1.25-percent salt solution as the diluent, were made in 50-ml. accounts, as follows: 1:8, 1:16, up to 1:2,048. One milliliter of each dilution was placed in each of 27 tubes, making a series of 27 tests of 10 tubes each, with the control serially diluted from 1:4 in the first tube to 1:2,048 in the tenth tube. Nine sets of dilutions were placed in the 37° C. incubator, 9 sets left at room temperature, and 9 sets placed in the refrigerator. To permit the tubes and dilutions to reach the desired temperature, each set was allowed to stand at room, refrigerator, and incubator temperatures for 1 hour before adding the colloidal mastic. Temperature ranges during the testing period were: room, 5° to 26° C. (minimum, 5° to 15° C.; maximum, 21° to 26° C.); refrigerator, 4° to 6° C.; incubator, 37° ± 1° C.

Three mixes of precipitated mastic were made each day. Each mix was precipitated by adding 2 ml. of 10-percent mastic solution to 18 ml. of 95-percent ethyl alcohol and rapidly pouring the 1-percent mastic solution into 80 ml. of freshly distilled water, with moderate agitation. One mix and one lot of distilled water were allowed to stand at each of three temperatures (incubator, room, and refrigerator) for 5 hours prior to mixing.

Three groups of dilutions of nine sets each were maintained at incubator, room, and refrigerator temperatures; the mastic solutions, which had been precipitated at the same three temperatures, were added to the dilutions; and the tests allowed to remain overnight at these temperatures. Thus, the effect of temperature on the sensitivity and reproducibility of the colloidal mastic test could be studied in relation to temperature at which dilutions were maintained prior to addition of colloidal mastic, temperature of the alcoholic mastic solution and water at the time of precipitation of the mastic, and temperature at which the tests were maintained overnight.

Results

Test results are shown in the accompanying table. The figure given for each dilution represents the arithmetic average obtained from the results of 10 tests performed in an identical manner on 10 consecutive workdays. The daily results did not vary more than $2\pm$ from that shown as average for any given dilution.

Discussion

The table indicates that the overnight temperature has the greatest influence on the sensitivity of the test, and that the most consistent, and most sensitive, results were obtained when the tests were allowed to remain overnight in the 37° C. incubator, regardless of the temperature at which the mastic was precipitated or the temperature of the dilutions when the mastic was added. Test results were most uniform when the tubes remained overnight in the incubator. Some decrease in sensitivity was noted when the tubes stood overnight at room temperature, and sensitivity decreased further at refrigerator temperature.

The temperature extremes of 37° and 4° C. were selected for evaluation, since it is not uncommon for seasonal changes to produce fluctuations of this magnitude. These incubator and refrigerator temperatures are normally maintained in most laboratories, and therefore the temperature of choice could be standardized without complicating routine conditions.

Temperature combinations and results

Dilution temperature ¹	Colloidal mastic temperature ²	Overnight temperature	Results ³
Incubator (37° C. \pm 1° C.).	Incubator	Incubator Room Refrigerator	5554321000 5553210000 5532110000
	Room	Incubator Room Refrigerator	5554321000 5543210000 5532100000
	Refrigerator	Incubator Room Refrigerator	5554321000 5543210000 5532100000
Room (5° to 26° C.).	Incubator	Incubator Room Refrigerator	5554321000 5543210000 5532100000
	Room	Incubator Room Refrigerator	5554321000 5542100000 5531000000
	Refrigerator	Incubator Room Refrigerator	5554321000 5543210000 5431000000
Refrigerator (4° to 6° C.).	Incubator	Incubator Room Refrigerator	5554321000 5542100000 5521000000
	Room	Incubator Room Refrigerator	5554321000 5542100000 5421000000
	Refrigerator	Incubator Room Refrigerator	5554321000 5543210000 5431000000

¹ Prior to addition of precipitated mastic.

² Alcoholic mastic solution and water at time of precipitation.

³ Average of 10 tests performed on each of 10 consecutive working days.

Conclusions

Use of a stable control serum in proper dilution as a constant source of specimen material indicates that a more uniform level of sensitivity and a higher degree of reproducibility will result with the colloidal mastic test if the tests are stored overnight in the 37° C. incubator.

Water Works in Civil Defense

By G. E. McCALLUM, C.E., MARK D. HOLLIS, C.E.,
and HARVEY F. LUDWIG, M.S.

The basic responsibility for civil defense correctly belongs to local people and local agencies. A philosophy of "self-help" is being forced upon us by the unparalleled seriousness of the world political situation. We realize that in time of disaster remote and higher-level agencies will be able only to help us help ourselves. Our interest here is to evaluate some of the benefits that have resulted from joint local, State, and Federal efforts to develop a water works civil defense program within the framework of the self-help philosophy.

The National Role

The Federal Civil Defense Act of 1950 is the first authorization ever made by the Congress for civil defense in the United States. Prior Federal civil defense activities, including the Office of Civilian Defense of World War II, were implemented only by Executive orders. The act specifically provides that responsibility for civil defense shall be vested primarily in the States and their political subdivisions; the Federal Government shall furnish coordination, guidance, and such other assistance as it is best qualified to furnish, including organization of mobile support and other interstate activi-

Mr. McCallum is chief of health emergency planning and Mr. Hollis, an Assistant Surgeon General, is chief sanitary engineer, Public Health Service. Mr. Ludwig is a sanitary engineer consultant of the Federal Civil Defense Administration. This paper was presented at the Arkansas Water and Sewage Conference, April 9, 1952.

ties, training of personnel, conduct of research, and procurement and stockpiling of necessary materials and supplies.

In the field of water supply, Federal activities are just beginning. The FCDA (Federal Civil Defense Administration), through its engineering and public health divisions, is in the process of publishing a fairly comprehensive technical manual, "Emergency Repair and Operation of Water Works in Disasters." Substantially a revision of the OCD World War II publication, "Water Works Engineering in Disaster," the new manual is organized into two parts: Part I discusses over-all water works management and the problems of maintaining quantity of supply; part II is concerned with the safety of the supply and considers the possibilities of contamination by special weapons (radiological, biological, and chemical), as well as by sewage. The manual is designed to serve the needs of both large and small water works for peacetime as well as wartime disasters.

Another important activity of the Federal Government is the performing of research to develop information needed to improve water works "defense" against contamination. While most of this work now has a security classification, it is expected that water works officials will be furnished with really pertinent information as it is developed, either by declassification or other mechanism.

Work is also beginning, under the leadership of the Public Health Service, on a national program for internal security for the water works industry, and the FCDA is planning a program for some stockpiling of pipe, chlorinators, and other emergency repair and purification equipment.

Regional Activities

Probably the most important work of the Federal Government awaits the establishment and filling of sanitary engineer positions in the nine FCDA regional offices. The FCDA budget has thus far permitted the employment of only a small sanitary engineer staff at Washington headquarters. This small group has been engaged in such civil defense sanitary engineering activities as water supply, sewerage, refuse disposal, milk and food sanitation, insect and rodent vector control, engineering aspects of emergency welfare services, mortuary services, radiological monitoring and decontamination, and engineering aspects of chemical and biological warfare defense. The appointment of regional sanitary engineers should greatly improve the development of effective collaboration between Federal, State, and local civil defense agencies, especially with respect to mutual aid and mobile support.

The importance of mutual aid and mobile support cannot be overemphasized. They are the basis of the planned pattern for American civil defense. The effectiveness of actual disaster relief operations will be largely determined by the efficiency with which skilled personnel and equipment can be mobilized and deployed on a regional basis. The FCDA regional office engineers, assisted by Public Health Service regional engineers and by key State personnel, such as State sanitary engineers, will be primarily responsible for planning such interstate programs and for exercising leadership in prosecuting them.

Local Activities

The basic civil defense job remains, however, for the individual water works to perform. Only it has the resources needed to achieve improvements in the physical plant, for assembly of necessary maps, tools, equipment, and other facilities needed for making emergency repairs, for organization and training of regular and reserve personnel, for integrating its program with other local civil defense programs, and for conducting test exercises with other communities in the region to check and improve the adequacy of the defense measures.

Of great importance is the interest shown by the smaller communities, which might well consider themselves relatively safe from attack and hence not greatly concerned, but which have the reservoirs of personnel and equipment necessary to the success of the mutual aid programs.

Importance of Water Supplies

Although classified as a utility service, a water works differs in important respects from such utilities as communications and power. Water works have two vital roles in disaster relief: Sufficient water must be made available for fire fighting; and, at the same time, a safe water supply must be maintained. Safe water has become so commonplace in our community living that even some of our health officials find themselves guilty of assuming that such safety, once achieved, will always be present. On the contrary, the development of atomic and other special weapons has made it more probable than ever that only extraordinary and carefully planned efforts can maintain the safety of supply in time of disaster.

Another important difference in the water works as a utility is the individual nature of water works systems. They are not so physically connected through a network that a load dispatcher can pool their resources and direct them to a point of need. By contrast, power utilities have virtually region-wide systems of mutual aid. They can very quickly, through prearranged plans, mobilize and apply their resources to a stricken area. In the water works field such collaboration must be developed, as already emphasized, through the mechanisms of mutual aid and mobile support.

Significance of Special Weapons

The continuing development of the ABCR (atomic, biological, chemical, and radiological) weapons imposes a continuing need for evaluating them as possible contaminants of water supplies. Such evaluations are difficult since even possibilities that seem remote must be considered. Radiological contamination of water to any serious degree, for example, is considered by many to be very unlikely; yet, because it is a possibility, much work has had to be done in

developing safe emergency levels of tolerance, quick and accurate methods of detection, and practical means for removing radioactive contaminants.

Of more real concern are the possibilities that biological and chemical agents might be employed to contaminate water supplies. The prospect that contamination of water with these agents might be attempted or accomplished as an act of war is difficult to evaluate, in the sense that there has been no actual use of these agents for this purpose, but in any case the prospect is extremely unpleasant. Continuing research studies must be undertaken to develop means for detecting and otherwise coping with these agents.

Although both chemical and biological agents might be used for contaminating water, the logistic problem may be much simpler with biological agents, such as bacteria. These, of course, are living organisms that can multiply in the body of a victim so that it is not necessary to introduce the total number of bacteria required to kill the host. A single *Brucella* germ may be sufficient to start brucellosis infection that may prove fatal. Thus far the most promising development in the realm of defense against biological contamination of water is the widely publicized membrane filter. In its present stage the membrane filter can scarcely be considered the answer to the problem of rapidly detecting biological warfare agents. It does, however, simplify and minimize the work of routine bacteriological testing, which in itself is of civil defense value, and further research may expand its range of usefulness.

Accrued Benefits

One of the primary results to date of the civil defense program in the local community is a new evaluation of the relative values of the various community services. The water works profession is faring excellently in this new thinking. Water works engineers have always been aware of the importance of their commodity to public living, but an increasing awareness of the enormity of the problem of civil defense is causing others to realize that this service is vitally important—that the lives and safety of

thousands of people may rest upon the ability of the water works to maintain an adequate and safe supply.

Such recognition is also, of course, helping to solve peacetime problems in the water works field. It is proving very valuable, for example, in assisting water works officials in obtaining funds and materials for much-needed improvements, especially since it can be shown that most of these improvements have direct civil defense significance. It has a stimulating effect on water works officials themselves, in interesting them to improve their operations to levels of higher efficiency.

Civil defense efforts in the water works field are also doing much to consolidate and improve the traditional relationships between water works officials and State and local health departments. These two groups have basic interests and responsibilities with respect to safety of water supplies, and in the past have satisfactorily managed to coordinate them, each working in its own manner. Now, however, both groups recognize that a more efficient and more intimate relationship must be achieved if their responsibilities are to be properly discharged during the critical period following attack.

Moreover, the concepts of mutual aid and mobile support have actually done much to reverse the attitude of local, State, and Federal officials toward each other. The local officials recognize how vitally important State assistance can be, and the State officials are thinking of Federal assistance in terms of an invited blessing instead of bureaucratic control. The Federal agencies, likewise, have become keenly aware, perhaps for the first time, of their own limitations. The prospect of having to mobilize for a total effort has forced their recognition of the local citizen as the most important cog in the machine.

In summary, we must remember that civil defense activities in the water works field, as in most others, must be accomplished essentially by a shifting of emphasis with respect to our "usual" activities. The maintenance of usual water works services during wartime is the responsibility of existing water works and public health agencies together with individual pro-

professional experts. The adaptation of water works to serve the extraordinary needs of disasters is the responsibility of civil defense. In view of the technical and professional requirements, the civil defense measures and services must continue to be the responsibility of the existing water works and public health agencies and individuals, but these agencies and individuals will perform their wartime disaster re-

lief functions under civil defense rules and regulations.

Civil defense in water works may, therefore, be said to be the job of everybody who is normally concerned with water works. This must not be interpreted as meaning that it is nobody's job. Each of us must do his part. Each of us must make his responsibility a part of his everyday business and affairs.

Relationship Between Inoculations and Poliomyelitis

The possible relationship of various types of inoculations and poliomyelitis has been the topic of much discussion and a number of papers since the 1950 reports from England. Last fall the State and Territorial Health Officers Association asked the Public Health Service of the Federal Security Agency to sponsor a study on the question and issue a clarifying statement. Subsequently, the Public Health Service, on March 14, 1952, sponsored a meeting of 42 poliomyelitis investigators, epidemiologists, pediatricians, allergists, and health officers. The National Foundation for Infantile Paralysis helped plan and participated in the conference.

The conference voted unanimously in favor of the conclusions contained in the following statement which has been accepted by the Public Health Service and is being transmitted to official health agencies, to the medical profession and to the general public.

There is no definite evidence that an increase in the number of cases of poliomyelitis has occurred as a result of injections of vaccines, drugs, and other medicinal agents. There is evidence that injections for the prevention of diphtheria, whooping cough, and possibly tetanus, when given during an epidemic of poliomyelitis, may, on rare occasions, localize the paralysis in the inocu-

lated arm or leg. There is no satisfactory evidence that other types of injections have any effect on the localization, frequency, or severity of poliomyelitic paralysis. In the small number of persons with localization of paralysis in the inoculated limb, the injections, for the most part, were given about 7 to 21 days prior to onset, which corresponds to the usual incubation period of poliomyelitis. This has raised the question as to whether or not inoculated persons have a greater chance of contracting poliomyelitis during an epidemic.

There is as yet no final answer to this question, but it is a fact that, even if there should be an increased chance, it is extremely small. Many thousands of poliomyelitis cases occur every year among children who have not had any injections during the preceding few months, and thousands of children have received injections for whooping cough, diphtheria, and tetanus during poliomyelitis epidemics and have not developed the disease.

Diphtheria, tetanus, and whooping cough are serious diseases which can be prevented by immunization. Unchecked, these diseases present a far greater hazard than poliomyelitis. The benefits derived from immunization against these diseases far outweigh the questionably small increased chance of contracting

poliomyelitis. However, even this questionable risk can be avoided by carrying out these immunizations when poliomyelitis is not epidemic in the community. There appears to be no good reason for withholding these immunizations during the summer months in communities that are not having an epidemic of poliomyelitis.

Furthermore, poliomyelitis is at all times so rare in infants under 6 months of age, and the danger from other infectious diseases, particularly whooping cough, is so great, that it is advisable to continue the immunization procedures for this age group even during a poliomyelitis epidemic. In adults also, poliomyelitis is relatively so infrequent, that when there is a need for immunizing or therapeutic injections, such injections should not be withheld.

Certainly no parent should object and no physician should hesitate to administer a needed antibiotic, drug, or other injection for treatment of disease at any time. When there is immediate danger from diphtheria, whooping cough, or tetanus, the preventive inoculations should be given to all threatened age groups even during a poliomyelitis epidemic. In the final analysis the decision as to when an immunizing or therapeutic injection shall be given to an individual patient must rest with the physician.

Ideas

Have You an Idea?

Something new? Different? Better? An easier way to get a job done? A simpler approach? More efficient? Cheaper? Faster?

As a health officer, hospital administrator, nurse, sanitarian, health educator—whatever your position—the day-to-day problems you face more than likely have counterparts in many other places. How you tackle your tasks may be of very real help to others in similar situations. And notes on how they handle their problems may help you.

This "Ideas" section is a place to exchange experiences and approaches. You, as well as your colleagues, will benefit when you send in your ideas.

—THE EDITORS

Pastoral Counseling

BIRMINGHAM, ALA. The idea of an interchurch center and pastoral counseling has grown out of a series of meetings with ministers sponsored by the Ministerial Association and financed by the division of mental hygiene of the State Department of Health. Of 400 ministers in Birmingham, 150 attended to discuss counseling problems with the aid of an expert from Duke University. An institute on "interprofessional relations" is being planned for the summer.

A tentative budget of \$10,000 per year has been agreed upon for the pastoral counseling center. The division of mental hygiene has indicated that it will supply approximately one-third of this amount in order to help get the project under way. The remainder of the funds

is being raised by individual churches, and the committee of the Ministerial Association hopes to convince the Community Fund of the city to invest money in the project. The committee is hoping to get this center opened during the fall of 1952.

Nutrition Flip Charts

ALBANY, N. Y. Nutrition in pregnancy is the theme of a series of flip charts recently completed by the New York State Department of Health. The flip charts are designed as an

A STUDY OF 1500 EXPECTANT MOTHERS IN NEW YORK STATE SHOWED:

11% NO milk.
 11% NO meat.
 56% NO eggs.
 39% NO citrus
 fruits.

aid to nutritionists and public health nurses in teaching classes of mothers.

The charts consist of 24 pages illustrated in color and enclosed in a carrying case, which can also be used as an easel for display purposes. Nutritionists give personal instruction to the nurses in the use of the flip charts, explaining that the flip chart is an aid to the speaker and to the audience. It provides an outline of the topic, and makes omission of important points unlikely. It also emphasizes and clarifies the speaker's points by providing visual material for the audience.

Although a film strip serves a similar purpose, nutritionists, nurses, and educators have chosen flip charts over film strips for several reasons. The charts are easy to use, requiring no special equipment and no operator. Then, too, there is no cleavage of audience and speaker created by darkening the room for film strips.

Cardiac Work Ability

WASHINGTON, D. C. A Cardiac Work Evaluation Unit is now functioning here as a means of gauging the work and living capacities of heart patients.

Each patient and his "work tolerance" are considered by a team consisting of the referring physician, a cardiologist, a clinical social worker, a vocational counselor, a representative of Goodwill Industries, a United States Employment Service representative, and the project coordinator.

For the work evaluation service, each patient must be referred to the unit by his or her own physician (private or clinic physician), and must be either unemployed or threatened with loss of employment because of a heart condition.

No medical treatments are provided in the service, and, though its goal will be to return cardiac patients to gainful employment, it is not an employment agency.

The program is sponsored by the Washington Heart Association as a community service. No charge is made to patients.

Trends in Illness and Mortality

By Selwyn D. Collins, Ph. D.

Illness and mortality data for the United States and several foreign countries have been collected and summarized to show long-time trends. An analysis of these trends indicates particularly the effect of wars and their aftermath on the public health.

Sources of Data

Much information is available on trends of mortality among persons of specific ages and by detailed causes, but very little is available on trends of illness over any long period of time. It is true that many of the acute infectious diseases, such as diphtheria, scarlet fever, poliomyelitis, and smallpox, have been reportable to health departments for many years, but the incompleteness of the reports is generally recognized by health workers. Even more incomplete are the reports for the diseases for which there is nothing in the way of treatment or prophylaxis to be gained by reporting them.

Some information on trends of illness may be obtained from the records of organizations that include groups of individuals for whom medical care is provided. Institutions of various kinds and private schools come under this category, but the largest such organization is the United States Armed Forces. Since

members of the armed forces receive complete medical care, a complete record of illness is usually made.

Other sources of continuous data on illness are the records of the various disability insurance associations in the United States and of compulsory sickness insurance in many countries of Europe. In most instances a doctor's diagnosis is available for each illness for which benefits are paid. Data from these sources, however, may be biased, since the regulations as to the types of illness covered and the minimum and maximum days of benefit allowable are changed periodically;

this is particularly true of compulsory insurance administered by governments.

Sickness surveys of various kinds also provide data useful in determining trends of illness. In 1880 and again in 1890, a question on illness was included in the United States census schedule. Questions about persons in institutions of various kinds, and persons with various types of physical handicaps, mental defects, and diseases have been recorded and tabulated in considerable detail in some State censuses since 1890. In Ireland the decennial censuses from 1851 to 1891 all included questions on illness, as did the censuses of 1881 and 1891 in Australia. In addition there were special surveys in a few cities in the 1890's, and fairly numerous sickness surveys have been conducted since 1915 (2).

There are several difficulties, however, in obtaining trends from special surveys: (1) Successive illness surveys even when made by a single organization are seldom done in the

Figure 1. Trend of illness and mortality from all causes except battle casualties, U. S. Army, 1820-1949.

Average rates exclude 1833, 1834, and 1936 as not available, and 1847-48, 1862-66, 1918-19, and 1942-45 as war years or unreliable. Data in this and following charts for 1820-1940 are for enlisted men; 1941-49 data include officers.

Dr. Collins is chief of the morbidity and health statistics branch, Division of Public Health Methods, Public Health Service. This paper is, in part, a revision and extension to more recent years of trend data originally published by Dr. Collins in The Annals of The American Academy of Political and Social Science, January 1945.

same manner and with the same questions; (2) even if the schedules and questions are uniform, the procuring of illness data by rather short interviews with the wife or head of the family is so difficult that careful training of the interviewer is an important factor in obtaining comparable data from different surveys; (3) since surveys are frequently made for special purposes, it is impracticable to use uniform schedules.

Armed Forces and Civilians

The longest series of data available on trends of both illness and death is for soldiers in the United States Army for the 130 years since 1820 (6). Figure 1 shows these data in average annual rates for 10-year

periods. The war years, which usually show a high mortality from disease, have been omitted in the computation of the average rates. For easier comparison, the death rates are plotted as deaths per 100,000 soldiers, and the cases, as admissions to sick report per 1,000 soldiers. (Logarithmic scale is used.)

It is seen in figure 1 that illness rates decreased greatly over the 130-year period, but deaths declined even more rapidly, especially in the peacetime years of the last decade. It should be pointed out that these cases and deaths are from disease and accident only and not from battle injuries, and that they are for troops stationed in the United States.

Moreover, the great majority of the soldiers are of the ages 20 to 30 years, which ages have low sickness and death rates.

Wartime Peaks

Figure 2 shows mortality and sickness data on a yearly basis for the armed forces, including data for the war years, but excluding data from both battle casualties and nonbattle accidents.

The mortality rates for disease only show striking changes; high peaks are seen for the Civil War, the Spanish-American War, and World War I. The predominant diseases causing the high case and death rates during the Civil War (1) and also the high 1898 peak of the

Figure 2. Trend of illness and mortality from disease only, U. S. Army, 1862-1949 (6); U. S. Navy and Marine Corps, 1897-1949 (7).

Spanish-American War were typhoid fever and the diarrheal diseases. The 1918 peak was almost entirely due to the great pandemic of influenza and pneumonia.

With the exception of two peaks, the death rates from disease in the Army declined rapidly after the Civil War until 1925. There was almost no decline, however, between 1925 and 1936; after that year there was a steep decline, which, with the exception of 1946 and 1947, continued until 1949, the last year for which data were available. The high rates of 1946 and 1947 may have been due in part to evacuees from overseas being brought to hospitals in the United States in 1945 and 1946.

The rates for the Navy and Marine Corps approximated those for the Army, although there was some decline in the period 1925 to 1936, but, as in the Army, a much steeper decline followed that year. Presumably a considerable part of this rapid decline in death rates in both services was due to the many improvements in therapeutics.

The lower right half of figure 2 shows cases of illness for armed forces personnel. There was a rather rapid decline in these rates from 1862 to 1896 when the build-up to the high peak of 1898 began; this decline continued at an even more rapid rate between the 1898 and 1918 peaks. It will be noted that the

sickness peaks of 1898 and 1918 were both relatively lower than the mortality peaks. From 1921 to 1939 the decline in sickness rates was less steep than in the earlier period. There was a considerable rise in the rate for the years 1940 to 1943, followed by a drop which was particularly rapid from 1946 to 1949.

The upper right half of figure 2 represents the annual days of sickness per person in the Army and Navy. The 1898 and 1918 peaks were definitely present although each extended into the next year with rates as high as or higher than for the first of the two high years. In this measure of illness, in terms of days lost from duty, there is considerably less downward trend than in the rates for either cases or deaths.

Figure 3. Trend of mortality from all causes except battle casualties, U. S. Army (6), U. S. Navy and Marine Corps (7), and civilian males of comparable ages, 1895-1949 (4, 5).

Comparison of Death Rates

Figure 3 affords a comparison of death rates for members of the armed forces with those for male civilians of approximately the same ages. To get a rate for a civilian group of comparable age with the military groups, simple averages of rates for males of the ages 15-24 and 25-34 were used. It is seen in the chart that the trend of mortality is roughly the same in the three groups, with the death rate among civilians in some periods tending to be somewhat higher than that among the armed forces personnel.

Illness Trends Among Industrial Employees

Data on the frequency of illness among industrial employees, as shown by absences from work, offer some measure of the trend of illness among civilians. The left half of figure 4 shows data for the approximately 3,000 employees of one large public utility establishment. From about 1920 to 1933 the rate of illness in this establishment tended toward a downward trend. There was little change in the rate from that date until 1940, when the rate for both males and females rose rapidly to a peak in 1946. After 1946 a definite drop occurred, but another small rise took place in 1950.

Data for a group of roughly 200,000 industrial workers (right half

Figure 4. Trend of illness among selected groups of industrial employees, United States, 1920-50 (3).

of fig. 4) show the same downward trend from about 1928 to 1934. The downward trend was followed by a steep rise in the rate for males to a peak of 147 cases per 1,000 employees in 1945. In 1949 the rate dropped to 95 per 1,000, which was the approximate level of the rate for 1940; however, the 1950 rate showed another small rise. Among women employees there was a similar rise to a peak of 258 per 1,000 employees in 1945, at which approximate level the rate remained for the next 5 years.

The sharp rises in illness rates during the war years may have been a result of the inability to hire persons who were in the best physical condition, since the most healthy individuals were at that time in the armed forces. As the pressure for employees declined after the war, persons not in the best of health were probably the first to resign or to be dropped from employment. It is not clear why the rates of severe illness (8 days or longer) among women workers did not decline like those among men for both severe and mild cases and like those for mild cases among women.

Tuberculosis Mortality

Figure 5 shows the trend of tuberculosis death rates in many countries of the world from about 1910 to 1950, with data lacking from some

countries at both ends of this period. A special attempt was made to determine the trend before World War I and also after World War II.

It will be noted that in nearly all of the countries where the intensity of the war was greatest (two top sections of chart), the tuberculosis mortality rates rose to a definite peak around 1918, the final year of World War I, and again around 1945, the climax of World War II. Following the World War I peaks the rates in most of these countries declined to a level that represents an approximate extension of the trend before the war. Similarly, after the peaks around 1945, the rates dropped rather sharply until by 1950 they were at or below the approximate level of a projection of the trend between the two wars.

The peaks for France and Belgium came in 1941, and the fairly small peak for Spain, in 1938. These dates are consistent with the trend of the war in those countries. England showed a smaller peak than the other warring countries, with the highest rate occurring in 1941.

In the countries that were at war but were geographically far removed from the areas of intensive fighting (lower right section of chart), the tuberculosis rates did not show any peaks that could be related to the war.

Although Scotland, Northern Ireland, Eire, and Finland (right mid-

dle section of the chart) were neither overrun by enemy forces nor particularly heavily bombed, the rates in these countries showed some increase in the years 1940-44.

In Portugal, Norway, Switzerland, Sweden, and Denmark, some of which were overrun but none of which were heavily bombed (lower left section of chart), there were evidences of retardation in the downward trends of tuberculosis mortality during the war years, but practically no peaks that could be attributed to war conditions.

Infant Mortality

The infant mortality rate is usually considered an index of economic and sanitary status which responds rather readily to environmental conditions. Figure 6 presents data that show particularly the influence of war conditions.

Noting first the two top sections of the chart, it is seen that there was in nearly every one of these countries a peak rate of infant mortality for some year during World War II. In a few countries, such as Austria, there was more or less of a build-up to that peak, but in other countries, there was little increase in the rate until the most intensive year of the war. For example, in the Netherlands there was a minor peak in 1941, but it was small compared with the high peak of 1945. Similarly, in

France there was a peak in 1940, but the peak in 1945 was higher. In both countries the rate declined rapidly in the 5 years following the peak, to a point not far from the projected interwar trend. In England and Wales there was a small rise in 1940 and 1941, but after that time the interwar downward trend continued at a slightly accelerated rate through 1950.

In the countries that were too far from the main theaters of war

to be heavily bombed (lower right chart), no wartime peaks in the infant mortality rates occurred.

The middle right section of the chart includes data for countries that were near the European theater of war, but were not overrun or heavily bombed. Finland had its high peak in infant mortality in 1940 and a smaller peak in 1944. The moderate peaks in Scotland came in 1941 and 1943.

Neutral countries which were in or

near the European theater of war, and some of which were overrun by enemy forces, experienced some moderate peaks in infant mortality. These peaks, however, occurred in the early part of World War II, and in none of these countries is there evidence of any exceptionally high peaks such as occurred in the Netherlands, France, Hungary, and Austria.

There seems to be a tendency toward fewer peaks in the countries

Figure 5. Trend of tuberculosis mortality, 1910-50 (8-10).

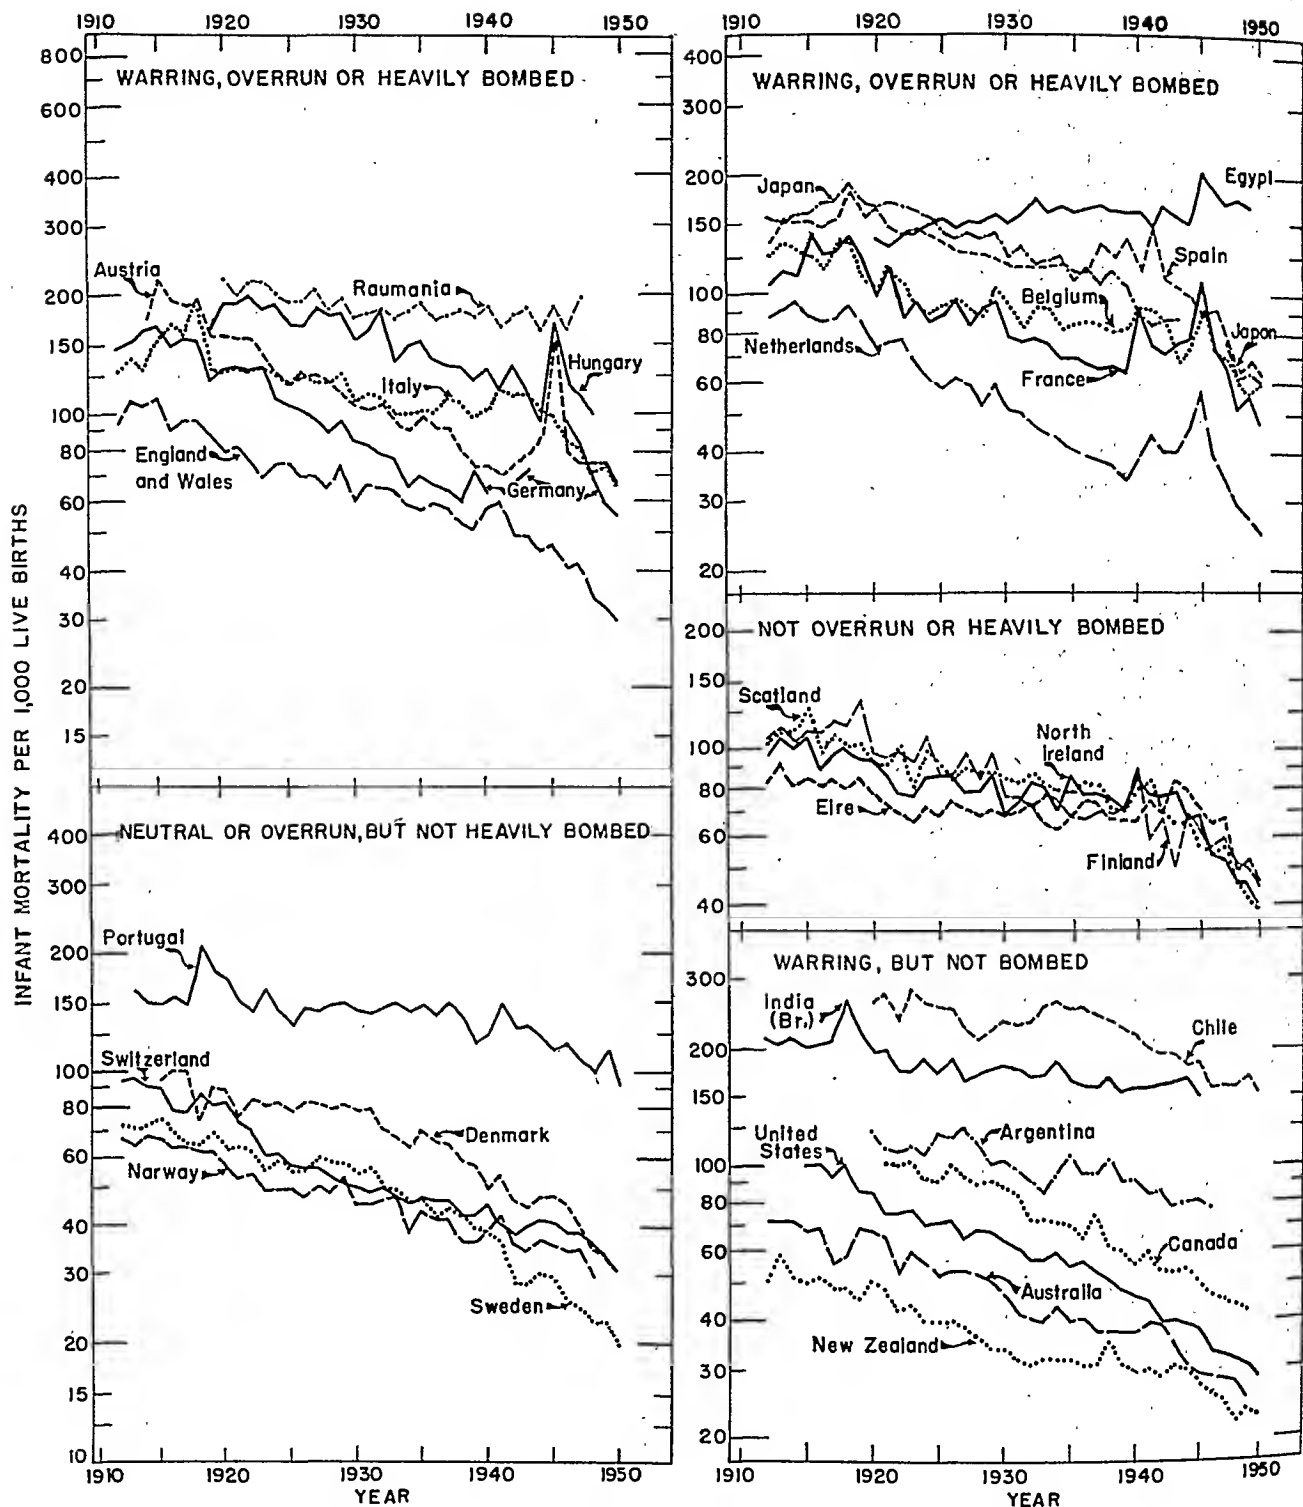

Figure 6. Trend of infant mortality, 1910-50 (8, 11).

where infant mortality is normally very high, such as Roumania, India, and Egypt.

Compared with the trend in tuberculosis mortality, infant mortality had a tendency toward a shorter

build-up to the high wartime peaks and tended to decline in slightly shorter periods to near the prewar level. The build-up in the infant mortality rates was sometimes manifest only in a leveling off of the

prewar trend, but the build-up in tuberculosis tended to be a definite rise in rates for several years preceding the peak.

Tuberculosis is an infectious disease and the patients are usually

sick for several years. In contrast, the sick baby does not count in infant mortality unless he dies within the first 12 months of his life. Since the severe conditions resulting from intensive warfare lasted several years, however, it would be expected that successive cohorts of infants experiencing the same severe conditions would each contribute something to higher death rates. However, nutrition is an important element in infant mortality, and food in many countries must have become more scarce as the intensity of the war was stepped up to its final culmination in 1945, when the highest infant mortality peaks occurred. Another factor of possible importance in saving infants may have been that an increased proportion of them were nursed rather than put on artificial feeding; even without an increase in nursing it may be that in the countries involved mothers normally nursed a high proportion of infants and thus kept infant mortality on a low level until the most severe years of the war.

Summary

Available data on trends of morbidity and mortality have been reviewed. Since 1820, both sickness and death rates in the armed forces have declined, but during wartime peak rates occurred. Data on the trend of illness among male and female industrial workers showed an increase in rates during World War II.

In the absence of data on morbidity from tuberculosis, the trend of mortality was shown. During both world wars there were high

peaks in the tuberculosis mortality rates for most countries at war or overrun by invading armies. Tuberculosis death rates built up in a 3- or 4-year period to high peaks which occurred at the climax of the war but which were followed by sharp declines to rates that represented the approximate levels of extensions of the trend between the two world wars.

Infant mortality showed similar trends except that the rises to peaks tended to occur in shorter periods. In general, war conditions seemed to affect infant mortality somewhat less than tuberculosis mortality.

Graduates in Sanitary Engineering

The number of graduates from undergraduate courses in sanitary engineering in the United States increased steadily from 1946 to 1950, but declined slightly in 1951. In 1946 there were 36 graduates; in 1947, 120; in 1948, 168; in 1949, 247; in 1950, 287; and in 1951, 244. The number graduated in 1951, however, is well above the average of 172 for the preceding 5-year period, according to the Division of Engineering Resources, Public Health Service.

Dr. Scheele begins second term as Surgeon General of the Public Health Service

Dr. Leonard A. Scheele, Surgeon General of the Public Health Service since 1948, took office for a second term April 6, 1952.

Dr Scheele is the seventh Surgeon General since the position was created by Congress in 1870. Surgeons General are appointed by the President from the regular commissioned career officers of the Public Health Service for 4-year terms. The Senate confirms their appointments.

A graduate of the University of Michigan (1931) and of Wayne University Medical School (1934), Dr. Scheele was commissioned in the Regular Corps of the Public Health Service on July 10, 1934. From 1934 to 1936 he was given assignments at foreign quarantine stations in San Pedro and San Francisco, Calif., and Honolulu, T. H. In 1936, he was assigned to the Maryland State Health Department for field experience in public health administration, serving as health officer of Queen Anne's County, Md.

In 1937, Dr. Scheele was assigned to the National Cancer Institute for

advanced training in cancer diagnosis, treatment, and research. After 2 years as a fellow at the Memorial Hospital, New York City, he returned to the National Cancer Institute in 1939 as a member of the staff. There he set up and administered the first cancer control program of the Public Health Service. World War II interrupted Dr. Scheele's cancer control work for 4 years. He returned to the National Cancer Institute in 1945 as assistant director and became director in 1947.

Dr. Scheele's wartime assignments began the day after the attack on Pearl Harbor, when he was assigned to the Medical Division of the Office of Civilian Defense. From 1943 to 1945 he was on detail to the medical department of the Army for duty in civil affairs and military government. His major overseas responsibilities were medical, public health, and welfare planning for civilian populations and control of epidemics.

Dr. Scheele served in the Mediterranean Theater of Operations on the 141 Force planning staff of Field

Marshal Lord Harold Alexander. With the Fifteenth Army Group, he participated in the campaigns in Sicily and the mainland of Italy. He also served on the staff of the Allied Control Commission for Italy.

In January 1944, he was transferred to the newly created Supreme Headquarters, Allied Expeditionary Force, London, as a medical member of staff planning for civil affairs and military government in Northwest Europe. He moved to the Continent after D-Day, with headquarters in Versailles and Rheims, France, and Frankfurt, Germany. Later Dr. Scheele served in Berlin as medical consultant for the Potsdam Conference and in the initial operations of the Allied Control Council.

Dr. Scheele was the chief delegate of the United States to the World Health Assembly meetings in 1949, 1950, and 1951, and is serving in that capacity at the Fifth World Health Assembly now meeting in Geneva. He was elected president of the Fourth World Health Assembly, 1951.

Prevalence of Arthritis and Rheumatism in the United States

By THEODORE D. WOOLSEY, B.A.

The importance of arthritis and rheumatism as common chronic diseases and as leading causes of suffering and disability scarcely needs to be demonstrated to anyone working in the field of public health or medicine. Numerous morbidity surveys have confirmed the significance of these diseases, and any general practitioner whose practice is not wholly confined to young people could doubtless substantiate it from his own experience.

Nevertheless, quantitative information in some detail is needed by public health organizations, rehabilitation agencies, and pharmaceutical firms for the planning of programs for the control of this group of diseases, for studying their epidemiology, and for many other purposes. Such information should include, as a minimum, data on the prevalence of the diseases to show the population groups most affected, the amount and severity of the disability caused, and the psychological and economic effect of the disability on the afflicted person and his or her family.

In 1951 the most recent statistics available on the prevalence of arthritis and rheumatism in the United States were 15 years old. From the results of the National Health Survey of 1935-36 (1) it had been estimated that there were at that time approximately 6,850,000 persons of all ages in the country with "rheumatism," including under that title all muscular rheuma-

tism, lumbago, arthritis, gout, "neuritis," and "neuralgia" (2). From the 5-year general morbidity survey in the Eastern Health District of Baltimore, 1938-42, more detailed statistics were compiled on the frequency and severity of disabling attacks and the degree of association of the prevalence of rheumatism and arthritis with various social and economic factors in an urban community. (See references 3, 4, 5, and papers referred to therein.)

New Data Collected

At the present time, with new possibilities opening up for treatment of the rheumatoid diseases, public health forces are mobilizing for concerted efforts to control these diseases and to alleviate their consequences. Hence, it is particularly important to collect up-to-date statistical information to serve the needs of research and control agencies.

Therefore, in September 1951 the Division of Public Health Methods undertook to obtain new estimates of the number of recognized cases of chronic arthritis and muscular rheumatism in the United States. An additional objective was to determine the proportion of these cases that had been seen by a doctor and the proportion that had entailed some reduction or change in the amount or type of work that the afflicted person could perform.

The data that were collected are limited in scope, but they are also broad in applicability because of the representativeness of the population upon which they were based. The procedure employed was to add six brief questions

Mr. Woolsey is a biostatistician in the Division of Public Health Methods, Public Health Service.

to the interview that is the basis of one of the regular monthly canvasses conducted by the Census Bureau's Current Population Survey. This survey is conducted in a very carefully designed sample of the population of the country. The sample is of the type known as a "probability" sample, which means that for estimates made from the sample it is possible to state the limits of error due to sampling. The interviewers of the Bureau of the Census periodically visit about 25,000 households scattered in 68 sample areas in 42 States and the District of Columbia. They obtain from some responsible person in the household information on employment, unemployment, and other economic and social characteristics of household members. The surveys usually cover only the population 14 years of age and over.

From this sample, estimates are made for the civilian population of the country as a whole, exclusive of the inmates of resident institutions such as homes for the aged, mental hospitals, and penal institutions. In September 1951 this population numbered approximately 109,000,000 persons 14 years of age and over.

The experience of the Public Health Service in household morbidity surveys indicates that the respondent for the family can give the interviewer reasonably reliable information on any specific diagnosis stated by a doctor. In the particular case of the rheumatism group of diseases, however, the average respondent probably does not distinguish clearly between the various diagnoses within the group. Consequently, this survey attempted to make only a rough division of the group into two classes—arthritis and rheumatism.

Design of the Interview

The interview questions on arthritis and rheumatism were worded as follows:

1. "This month we are making a study to find out how many people have arthritis or rheumatism or other ailments of that type, such as gout or lumbago. First of all, I'd like to check the persons in the household who have any trouble of that sort."

(All persons 14 years of age and over who were reported to have any form of arthritis or

to have fibrositis, gout, lumbago, myositis, or any form of rheumatism, *except* rheumatic fever or rheumatic heart disease, were identified. All succeeding questions dealt with the persons thus identified.)

2. "Has . . . ever been treated by a doctor for this condition, or talked to a doctor about it?"

3. If *yes* in 2: "Has a doctor ever told . . . what his (or her) condition is called?"

4. If *yes* in 3: "What did he say it was?" (The reply was coded by the interviewer as "A," if the response indicated any form of arthritis; as "R," if the response indicated fibrositis, gout, lumbago, myositis, or any form of rheumatism *except* rheumatic fever or rheumatic heart disease; as "OT" if any other disease was mentioned, such as "neuritis.")

5. "Has . . . had to cut down on or change his (or her) work or other usual activities in any way on account of this trouble?"

(When a *yes* answer was given the interviewer recorded the type of change that was made. Some changes that were mentioned were later edited to *no*, because they seemed to represent adjustments that were only temporary or were optional on the part of the afflicted person. An example of the latter: "I never lift heavy weights whenever I can help it.")

6. "Has . . . had any definite signs of this ailment within the past month?"

From the answers to these questions by the respondents for the households in the sample, estimates were made of the number of persons in the civilian noninstitutional population of the United States, 14 years of age and over, who would have been reported to have arthritis or rheumatism, to have seen a doctor for the condition, and so forth, if every household in the United States had been visited. A few of the major results of the survey are shown in the tables and graphs that follow. A more detailed account of the survey findings will appear in a later report.

Since the estimates are based on a sample, they are, of course, subject to sampling error; where the frequencies in the tables are small this error may be relatively large. Hence, the smaller frequencies in the tables and the percentages where the base is likely to be small (in particular, percentages based upon the non-

white population) should be used with some caution. In the description of the survey results that follows it may be assumed that comparisons cited are statistically significant—unlikely to be attributable solely to random sampling fluctuations—unless otherwise noted. As in any survey, there are also errors due to biases in response. However, the careful training given to Census interviewers for the Current Population Survey, their experience with many different kinds of questions, and the preliminary testing of all questions used in this survey give a basis for confidence that such errors are not large.

Estimated Cases

The persons reported by the family respondent as having arthritis or rheumatism may be classed as "presumptive" cases. These totaled an estimated 10,104,000 persons aged 14 years and over in the United States (table 1). A comparison of this figure with the corresponding estimate from the National Health Survey of 1935-36 is, unfortunately, unreliable as an indication of trend. The questions asked and the manner of conducting the two surveys differed. Furthermore, the earlier survey covered a population that was almost entirely urban.

In answer to the question about what the doctor had called the condition, the respondent sometimes mentioned a diagnosis which was not considered to be a form of arthritis or rheumatism in this survey. This happened in 484,000 (4.8 percent) of the presumptive cases. Such cases might easily be counterbalanced by definite cases of arthritis or rheumatism that the family failed to report because they were not recognized as cases for one reason or another. A more important reason for including these cases in the tables is that the total of all cases reported by the families (presumptive cases) is the figure that is most nearly comparable with that obtained from other family studies. Another 3,206,000 cases (31.7 percent) must be considered to be in the doubtful class either because the person had not seen a doctor at all (2,540,000 cases) or because the family did not know what the doctor's diagnosis was (666,000 cases). There were, however, an estimated 6,414,000 cases (63.5 percent) which had been seen by a doctor and identified by him as arthritis, rheumatism, gout, lumbago, myositis, or fibrositis. These may be described as "diagnosed" cases, although in some instances it is likely that the statement made by the doctor represented only a preliminary opinion. In about 70 percent of the 6,414,000 cases the respondent's de-

¹ Estimates are derived from a sample survey and are therefore subject to sampling variability, which may be relatively large where the quantities shown are small.

² Arthritis includes any diagnosis reported by the family containing the word "arthritis"; "rheumatism" includes the terms: rheumatism, gout, lumbago, myositis, and fibrositis; "other" includes all other terms and diagnoses and, hence, consists of terms and diagnoses not classified as arthritis or rheumatism in this survey. This last category is included in the tables because the total of all cases reported by the families is the figure that is more nearly comparable with that obtained in other family studies.

scription of the doctor's diagnosis contained the word "arthritis." In the remainder it was simply "rheumatism" or one of the other terms that were included under that heading in this survey.

It should be emphasized that the estimate of 6,414,000 so-called "diagnosed" cases of rheumatism and arthritis among persons 14 years of age and over was obtained from information supplied by lay respondents, reporting what they believed the doctor had said. A sample of the population carefully screened for these diseases and subjected to all the procedures necessary for a firm diagnosis might give a substantially different figure. However, a screening and diagnostic study of that type would of necessity be smaller and less broadly based. It is only by linking such surveys as the one described here with more intensive studies of smaller groups that we shall be able to estimate the number of persons in the country with unquestioned cases of rheumatoid or degenerative arthritis or other forms of rheumatism. The survey of September 1951 will therefore be useful as a means of calibration, provided the identical questions used in the national survey are also incorporated in the smaller surveys to provide the link.

More Women Afflicted

Table 1 also shows the percentage distribution of the cases in these various categories for males and females separately and the percentage of the civilian noninstitutional population 14 years of age and over falling into each class, that is, the prevalence rate per 100 population. The prevalence of presumptive cases is 9.3 percent; of all cases seen by a doctor, 6.9 percent; and of diagnosed cases of rheumatism and arthritis, 5.9 percent. The prevalence among females is considerably higher than among males. There seems to be a consistency in this sex difference in all the prevalence rates in the table. It is worthy of note, however, that while the percentage prevalence for females exceeds that for males by approximately 80 percent for the diagnosed cases identified as "arthritis," the sex difference for cases identified as "rheumatism" is not statistically significant.

Figure 1 illustrates not only the contrast

Figure 1. Prevalence of "diagnosed" arthritis and rheumatism by sex and age in the civilian noninstitutional population of the United States, September 1951.

between the sexes in the prevalence of diagnosed arthritis but also the sharp increase with age in the prevalence of both arthritis and rheumatism.

By no means all persons reported as cases by the families in the survey were sufficiently disabled to cause any material reduction or change in work or other usual activities. The kinds of changes or adjustments that were considered of sufficient importance to be counted included: giving up gainful work or housework entirely; changing to a lighter or more suitable type of work, such as a type that did not require use of the fingers; giving up all heavier parts of the work or of household chores; changing to part-time or occasional work; moving to a warmer climate; changing the conditions of work, for example, from night to day shift; giving up athletics entirely (for a young person). Among those who had seen a doctor, 31 percent had made some such change in the amount or type of work or other usual activities (table 2). The corresponding figure for those who had not seen a doctor was 13 percent. Thirty-four percent of the diagnosed cases identified as arthritis and 29 percent of those identified as rheumatism

^{1, 2} See footnotes, table 1.

reported a change in the amount or type of work.

The percentage of the population in each age group with diagnosed cases of arthritis or

rheumatism is shown in figure 2. The upper line shows all such cases, while the lower line is for those diagnosed cases in which the person had made a change in the amount or type of

his, or her, work. An indication of the magnitude of the economic aspects of this public health problem may be seen in this graph. From 1.5 to 5 percent of the population in the upper working ages (45 to 65) have had to give up entirely, cut down on, or make some other significant change in their work or other usual activities because of ailments described to the families by the attending physicians as some form of arthritis or rheumatism. If all presumptive cases were included, the figure would, of course, be higher.

Higher Prevalence Rates in Rural Areas

Although only a few of the survey results bearing upon the distribution of these diseases in the population can be shown here, certain variables that appear to be particularly important have been included in tables 2 and 3. A review of some of the points of interest in these tables brings out the following relationships:

1. The proportion of all presumptive cases that had been seen by a doctor was significantly lower in the rural farm population than in

either the urban or rural nonfarm groups. In the two latter population groups the proportion is about the same (table 2).

2. The proportion of cases seen by a doctor was lower for the nonwhite population than for the white (table 2).

3. The prevalence of diagnosed cases of arthritis is higher in the population living in rural areas than it is in the cities. The same holds true for cases identified as rheumatism. The difference between rural nonfarm and rural farm populations in the prevalence of diagnosed cases of rheumatism and arthritis combined is not great enough to exclude the possibility that it is a result of random sampling variation. However, the evidence on occupational differences supports the hypothesis that rheumatism and arthritis of all forms combined are more prevalent in the population of farm areas. Since these differences in the urban and rural prevalence of diagnosed cases are partly a function of the differing proportions of cases seen by a doctor, it is also worth noting that the prevalence of all presumptive cases is also highest in the rural farm group and lowest in the urban (table 2).

4. The prevalence of presumptive cases in the nonwhite population is not significantly higher than the prevalence in the white population (table 2).

5. The proportion of presumptive cases for which a change in the amount or type of work or other usual activities was reported was higher among rural farm families than among urban or among rural nonfarm families. Furthermore, the proportion of cases associated with a change of this sort was higher in the nonwhite population than in the white population (table 2).

6. Age-adjusted prevalence rates, that is, rates that have been adjusted to make allowances for differences in the age distribution of the population being compared (table 3), show that the percentage of persons engaged in farming reported as having rheumatism or arthritis was higher than that among employed persons in general. On the other hand, "professional, technical, and kindred workers" and "clerical and kindred workers" tended to have a lower prevalence when compared with all employed persons of their own sex. These

² Age-adjusted by the "indirect method" to the total employed population of both sexes.

³ Percentages not computed because of small frequencies.

figures suggest hypotheses that should be tested in more intensive studies; without information on such factors as income, education, and diet, it is impossible to say whether the differences are due to occupation per se. The statistics suggest, however, that outdoor occupation may be a factor in determining the prevalence of arthritis and rheumatism.

7. In every occupational group in which both men and women are represented in substantial numbers, the age-adjusted prevalence rate for females is higher than that for males. Though not all of the differences are statistically significant, the pattern is consistent. Thus, the sex differences commented upon earlier cannot be entirely accounted for by the dissimilarity in the usual activities of men and women in general (table 3). Small differences between the rates for various occupations shown in this table, however, should be interpreted with caution because the sampling error is relatively large in some groups.

Summary

Some findings from the September 1951 survey of arthritis and rheumatism are presented. From the survey data it has been estimated that

there are approximately 10,104,000 persons 14 years of age and over in the United States who believe that they have arthritis or rheumatism. About 75 percent of these persons have seen a doctor about their condition. An estimated total of 6,414,000 have been told by a doctor that their condition was arthritis, "rheumatism," gout, lumbago, myositis, or fibrositis. About 5 percent of the 10 million persons who believe that they have one of these diseases apparently do not, if they reported correctly what the doctor told them; and others must also be considered doubtful cases for one reason or another. However, about one-fourth of the 10 million cases had made some significant change in the amount or type of work they performed or in their other usual activities. Sex, race, age, urban or rural residence, and occupation are examined as factors affecting the prevalence of the diseases.

Dr. Otis L. Anderson New Chief of Bureau of State Services

The appointment of Assistant Surgeon General Otis L. Anderson as chief of the Bureau of State Services of the Public Health Service was announced by Surgeon General Leonard A. Scheele May 3, 1952. Formerly associate chief of the Bureau of Medical Services, Dr. Anderson succeeds Dr. Joseph W. Mountin, who died April 26.

Dr. Anderson entered the Commissioned Corps of the Public Health Service in 1930, after interning at the Public Health Service hospital in Baltimore, Md.

After serving on the staffs of Public Health Service hospitals in Boston, Ellis Island, and Norfolk, he was assigned in 1936 to the Virginia State Department of Health to direct its venereal disease control program. In 1940, he was named Public Health Service venereal disease control consultant to health departments and industries in Michigan, Minnesota, Wisconsin, Iowa, Illinois, Indiana, and Ohio, and in 1941 he undertook the direction of the industrial phase of the national venereal disease control program.

Dr. Anderson was appointed assistant chief of the Division of Venereal Disease in 1942. He was assigned in 1944 to New Orleans to direct the Public Health Service programs in Louisiana, Florida, Alabama, Mississippi, South Carolina, Georgia, and Tennessee. Later in 1944, he returned to Washington to administer the 23 Public Health Service hospitals. He was appointed associate chief of the Bureau of Medical Services in 1949. Dr. Anderson is a fellow of the American Medical Association and of the American College of Physicians, a diplomate of the American Board of Preventive Medicine and Public Health. He is a member of the American Public Health Association, the American Hospital Association, and the Association of Military Surgeons.

Birth Registration Completeness United States, 1950

By SAM SHAPIRO, B.S., and JOSEPH SCHACHTER, B.B.A.

Preliminary results of a recently completed nation-wide test of birth registration indicate that birth records are now filed by attendants and hospitals for about 98 percent of the babies being born. This represents an important advance since 1940 when only 92.5 percent of the births were registered. Progress made during this period has virtually eliminated underregistration as a practical problem in more than half the country and has sharply reduced the problem in nearly all other areas.

The registration completeness test was conducted in connection with the 1950 Decennial Census of Population and Housing through the cooperative efforts of the Population and Housing Division of the Bureau of the Census, the National Office of Vital Statistics of the Public Health Service, and the State, Territorial, and independent city registration offices. From the standpoint of birth registration, the primary purpose of the test was to obtain current measures of registration completeness for States and local areas on a comparable basis. The chief interest of the Bureau of the Census in the project has been to determine variations in infant enumeration completeness by social and economic groups and to find out reasons for failure to enumerate infants.

Mr. Shapiro is chief of the natality analysis branch of the National Office of Vital Statistics and directed the 1950 test of birth registration completeness. Mr. Schachter is a statistician in the branch and had immediate supervision over many phases of the test.

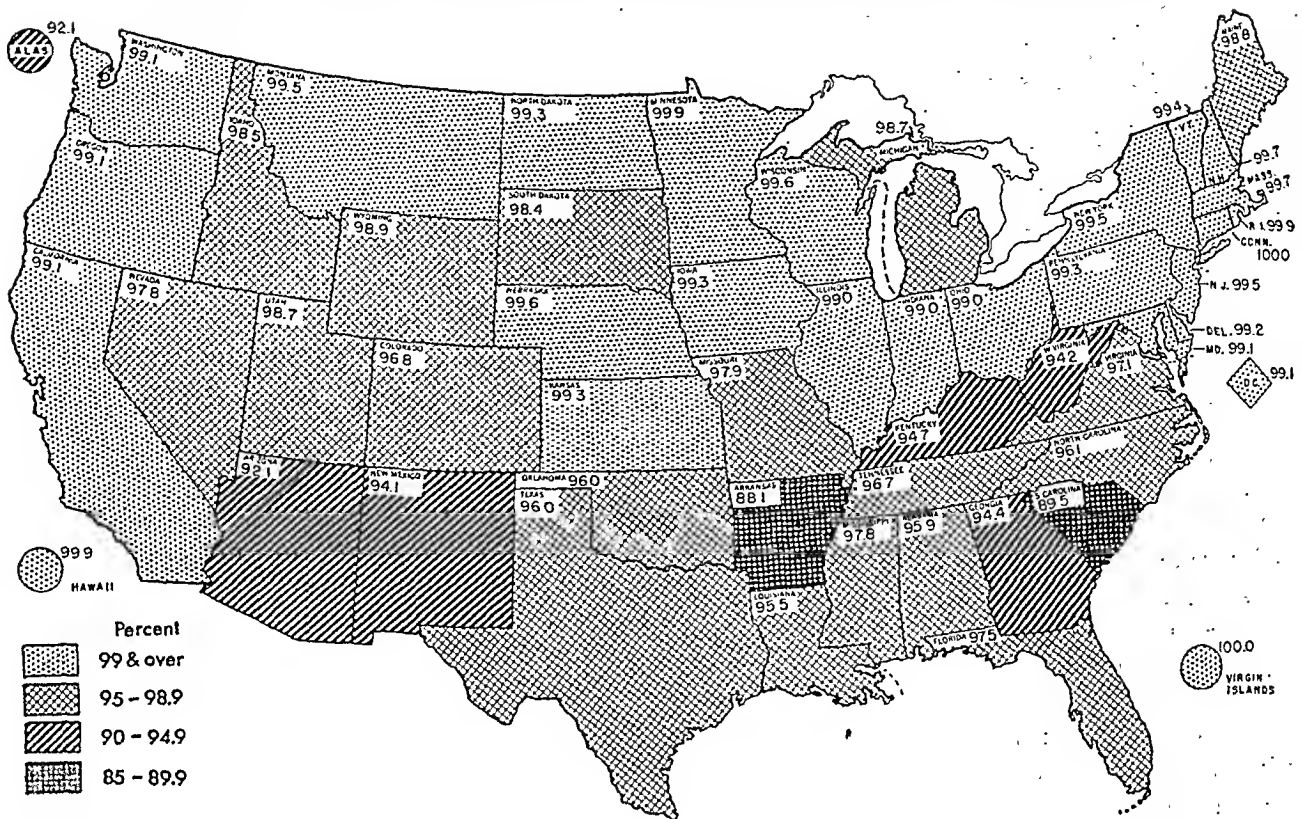

Background

In the past 30 to 40 years, the birth registration system has become one of our indispensable public institutions. A birth record is now of great importance to most people. It is called on frequently to prove age, birthplace, and parentage for such purposes as entering school, obtaining employment limited to citizens, and qualifying for pensions or social security benefits.

The value of the birth record to the individual is paralleled by its importance as a source of data for health workers. The record is used in many communities for reaching families needing public health nursing services or education in the care of the infant. Statistics derived from the record have been an essential and effective tool for planning and evaluating programs for the reduction of infant and maternal mortality. In fact, the recognized need for these statistics stimulated the organization of the birth registration system in the United States. Today, the allocation of resources to deal with aspects of infant mortality such as prematurity (immaturity) is greatly dependent upon information gathered from the birth record.

The use of birth statistics extends far beyond the health field. Available data play a part in the baby food manufacturer's plan for marketing his product, in the city or county school commission's estimate of future needs for classrooms, and in the housing expert's recommendation for new construction required to meet the trend in family size. In addition, these statistics are used extensively to study and in-

Figure 1. Percent completeness of birth registration, 1950 test (preliminary).

interpret population changes for long-range social and economic planning.

To a great extent, the capacity of the registration system for meeting these diverse demands is measured by the completeness with which births are registered. This has been recognized for many years. The history of the formative years of the national birth registration area, 1915 through 1933, is replete with instances of major efforts by health, welfare, and civic groups to insure the registration of all births (1). Despite the striking success of these campaigns, the broad range of cultural and ethnic groups within the population and the remoteness of many parts of the country from urban centers prolonged the period during which underregistration was a serious problem.

This was illustrated by the results of the first nation-wide test of birth registration completeness in the United States conducted in conjunction with the 1940 Decennial Census of Population and Housing. In 14 States only 80.0 to 89.9 percent of the births were registered and 2 States had even lower percentages (2). The results also demonstrated that registration was

especially poor among groups most likely to require public health services that depend on the birth record for case finding. Fully a fifth of the babies born to mothers with little or no education were not registered, and a seventh of the births to farm residents were missed.

Further examination of the 1940 data showed that while the registration problem centered among attendants taking care of home deliveries, registration of hospital births also lagged in some places. These findings, together with figures for local areas, formed the basis for State campaigns directed toward attendants and local registrars to improve registration. However, before all of the necessary actions could be taken, State and local vital statistics offices were overwhelmed by the war demands made upon them for copies of birth certificates. In addition, requirements of the armed forces and war-connected industries rapidly depleted their staffs.

The same factors that diverted efforts from organized promotional activities to improve registration also resulted in making millions of young adults more conscious of the importance of the birth record. Never before was

such a high premium placed on having a birth certificate. Citizenship had to be established to qualify for jobs in defense industry; applications for food ration books for new-born children frequently had to be accompanied by birth records, and birth certificates of dependent children often had to be submitted by servicemen in applying for family allowances. Moreover, hospital facilities for obstetrical care increased, and each year the proportion of births being delivered at home diminished.

After World War II, State offices of vital statistics once more turned their attention to specific measures for curtailing underregistration. While it was generally believed that the net effect of wartime conditions had been to improve the situation, an objective measure of the extent to which underregistration remained a problem was needed to direct these activities. The 1950 test of registration completeness was designed with this in mind.

With the completion of the test, the situation in counties and cities has become clarified. The results are helping registrars localize areas requiring attention, determine the reasons for

the remaining underregistration, and take remedial measures. For areas where registration incompleteness is still significant, the test also provides factors for correcting statistics derived from birth records.

Registration in 1950

The 1950 birth registration test indicated that 97.8 percent of the infants born in the early part of that year had birth certificates on file in vital statistics offices. In 23 States and the District of Columbia, birth registration completeness was over 99 percent and in only 7 States was it lower than 95 percent (fig. 1 and table 1).

Seven out of eight infants included in the test were born in hospitals, and all but a few of the hospital births were registered. For births delivered at home, however, registration was not nearly as complete. Nationally, only 88 percent of these births were registered, and in some States the proportion was considerably lower. Because of the consistent pattern of higher registration of hospital births throughout the

¹ All percentage changes are relative changes from the 1940 measures of registration completeness. Decreases are indicated by minus sign (-). ² Based on 25 to 99 records. Sizeable variations in percentages based on these frequencies may arise from random factors. ³ Not computed. Number of test records less than 25. Percentages based on so few records subject to considerable error. ⁴ Not applicable. ⁵ Not available. ⁶ Registration test in process.

NOTE. 1950 percentages show results of registration completeness test covering January-March 1950 live births; 1940 percentages, results of similar test covering live births in December 1939 and January-March 1940.

country, the extent to which mothers used hospital facilities played an important part in determining a State's total registration completeness. Figure 2 shows that the proportion of births occurring in hospitals varied considerably from region to region and was lowest in the southern geographic divisions.

About two-fifths of the births occurring at home were attended by midwives, relatives, or neighbors. These attendants registered 85 percent of the births they delivered as against 91 percent for physicians attending home deliveries (tables 2 and 3). Nonphysicians (predominantly midwives) were used far more often in the South Atlantic, South Central, and Mountain States than in other parts of the country. In a number of States these attendants took care of more births at home than did physicians, and in some areas they had a better record of registration.

By comparison, in the 24 States of the New England, Middle Atlantic, North Central, and Pacific areas, fewer than 5 births in every 1,000 were delivered by nonphysicians, with about two-fifths of them unregistered. The large underregistration in this group is explained in part by the fact that the attendant was often a neighbor or relative with little or no knowledge of the responsibility for filing a birth certificate.

Of the white births in the test, 98.5 percent were registered as against 93.4 percent of the nonwhite. A closer examination of the situation indicates that there was no difference between the two race groups in registration completeness of births "at home" and only a slight difference with respect to the "in hospital" births. However, when hospital and nonhospital births are combined, registration is found to be more complete in the white group than in the nonwhite because of the more frequent occurrence of white births in hospitals.

More than nine-tenths of the nonwhites were Negro, the remainder being about evenly divided into "Indian" and "other." The last group consists mainly of births to parents of Chinese or Japanese extraction. Of the nonwhite groups, the Indian had the poorest record of registration completeness (85 percent). Nonphysicians attended over one-fifth of the Indian births and filed certificates for less than half (44 percent) of the infants they delivered. In

Figure 2. Proportion of births occurring in hospitals for each geographic division, 1940 and 1950.

the "other" category, registration completeness was over the 97-percent mark. Most of these births occurred in areas where extensive use is made of hospital facilities for maternity care.

National Changes Since 1940

A comparison of results from the 1940 and 1950 registration tests shows that substantial gains were made during the intervening years. For the United States as a whole, the relative improvement was 5.7 percent—registration completeness rising from 92.5 percent in 1940 to 97.8 percent in 1950 (table 1).

About four-fifths of the increase is explained by the trend toward use of hospital facilities for obstetrical care (3). In 1940, about half of the confinements were in hospitals; by 1950 this proportion had increased to seven-eighths of the total (fig. 2). If the continuing efforts of State and local registrars to obtain complete

registration among hospitals and among home attendants had succeeded only in maintaining the 1940 levels in each group, registration completeness for the country would have risen to 96.8 percent because of the change in the proportion of hospital births.

The remaining portion of the improvement was due to moderate increases in registration of both "in hospital" and "at home" births. During the period of the 1940 test, birth registration completeness of hospital births was already high—98.5 percent (4). Hence, although States with near perfect registration of such births retained their high standards and other States

were able to approach close to the 100 percent mark, the total improvement was necessarily modest.

With respect to deliveries at home, registration completeness in 1940 was only 86 percent, but here, too, the increase was small—2 percent. To some extent, this limited improvement is explained by the change in composition of attendants delivering babies in the home. Doctors, whose registration practices are generally better than those of the nonphysician group, took care of about three-fifths of the home deliveries in 1950 as against four-fifths in 1940.

NOTE. Registration completeness measured by percent infant cards matched.

Figure 3. Percent completeness of birth registration, 1940 test.

Improvement Among the States

Birth registration improved in virtually every State during the 1940's. States varied in completeness from 76 percent to over 99 percent in 1940, but by 1950 the range was cut in half. To the ranks of the three States that had 99 percent or higher registration completeness in the earlier period were added 20 States and the District of Columbia (fig. 3).

Large gains were made in most of the southern States; nearly all of which were well below the 90-percent point in 1940. Tennessee, with only 80 percent in that year, improved by 20 percent; Arkansas, Georgia, and South Carolina, by 15 to 16 percent; and Alabama, Louisiana, North Carolina, Oklahoma, and Texas, by at least 10 percent.

In all States, the increase in the proportion of births occurring in hospitals was an important factor in the change. However, for some States, particularly those in the South, this by no means tells the whole story. In a few, registration of hospital births during 1940 lagged substantially behind the national average. The

improvement that followed brought these areas much closer to the United States figure.

Promotional efforts among midwives and prospective parents also played a large role in the advance made in registration completeness in the southern States. These took varied forms, but in most cases they were linked to public health programs. For example, training sessions organized in a number of States under the direction of public health nurses to teach midwives maternity care were used to instruct them on the preparation of certificates.

In Alabama, Louisiana, Mississippi, and South Carolina, attendance at prenatal clinics served as a point of contact with expectant mothers to establish a check on the filing of a birth record. Post cards were given to these women with the request that they be completed and returned to the health department as soon as possible after the birth of the child. Information received in this way was then used to find out whether the attendant had registered the birth, and follow-up action was taken to remedy omissions of registration. Other steps taken by States included such measures as the

Table 3. Registration completeness by race and person in attendance at birth for selected States, 1950

NOTE. Registration completeness measured by percent infant cards matched.

dual registration system in Georgia which requires both the parent and the attendant to report the birth.

While registration completeness of births at home increased throughout the South, decreases occurred in almost all other parts of the country. Some of the decreases were small and could be ascribed to random factors. In several States the test figures indicate a substantial decline, but a much higher proportion of the home deliveries in these areas were attended by nonphysicians in 1950 than 10 years earlier. As previously mentioned, nonphysicians in most of the areas outside the South have infrequent contact with the registration system and generally know very little about filing a birth record.

Improvement by Race

Registration in the nonwhite races improved considerably during the 1940 decade. As a result, the wide-difference in registration completeness between the white and the nonwhite group that existed in 1940 was substantially reduced. From 82.0 percent in that year, the proportion of nonwhite infants for whom certificates were being filed rose to 93.4 percent in 1950. The corresponding change for the white group was from 94.0 to 98.5 percent (table 4).

In the white group, the improvement in registration was related to the more frequent use of hospital facilities in 1950. Registration of hospital births, already very high in 1940, approached even closer to 100 percent. There was practically no change in the completeness of registration of "out of hospital" births. But, in the 1950 test, 92 percent of the white births occurred in hospitals as against 56 percent in the earlier test.

On the other hand, nonwhite registration improved by 2 percent for hospital births and by 14 percent for births delivered at home. The importance of the latter improvement is indicated by the fact that even in 1950, nearly half of the nonwhite births occurred at home. Promotional efforts of many of the southern States were directed primarily toward this group.

The figures on registration of Negro births and the reasons for the improvement between 1940 and 1950 are practically identical with those for the total nonwhite group (table 5). Among the Indian births, registration completeness advanced from the very low point of 68 to 85 percent (5). The more frequent occurrence of births in hospitals in 1950 was, of course, partly responsible. A number of special administrative and procedural actions taken by the States during the decade to reduce under-registration in this race group also contributed to the change.

Methodology

The 1950 birth registration test was limited to infants born during the 3-month period, January 1 through March 31, 1950. Two sets of independently collected records for these infants were compared to obtain measures of registration completeness, that is, birth records on file were matched against infant cards filled out by Census enumerators during the Decennial Census of Population and Housing in April 1950, for enumerated children born in the first 3 months of the year. Because of the confidential nature of the infant cards, they were handled only by Census personnel or special agents of the Bureau of the Census (for discussion of methodology in the 1940 test, see reference 2).

The matching operation consisted of three major phases.

1. *Matching at the National Office of Vital Statistics.* A punched card containing alphabetical and statistical data was prepared by the National Office of Vital Statistics for each birth record and infant card in the test. The punched cards were collated mechanically using various combinations of common identifying information. When data on these cards were inadequate to establish a match, copies of the original records were examined for confirming evidence.

About 94 percent of the 780,000 infant cards in the test were matched during these operations. (The 780,000 cards do not represent the exact number of infants enumerated in the census since in some cases the enumerator recorded the child on the basic population schedule but failed to fill out an infant card.)

2. *Mail survey.* Unmatched infant cards were included in a mail survey designed to verify and correct information on the residual group. The questionnaire was sent to parents and in special cases to welfare organizations and hospitals. Replies to the initial mailing and follow-up letter were received for about 80 percent of the records. These responses resulted in additional matches and in the elimination of infant cards for children born outside the test period.

3. *State searches.* The 30,000 infant cards still unmatched after the mail survey were sent to State, independent city, and Territorial registration offices for searches against their files. Registrars were authorized to use other sources of information within the limitations of Census and State regulations. Matching records were located for almost half the infant cards sent to these offices. Problems of identification created by illegitimacy, adoption, and other situations resulting in name changes were frequently resolved in this phase.

Preliminary Nature of Test Results

All figures now being released for the 1950 test are preliminary. Final results will become available in a few months after States have had an additional opportunity to search their files and contact agencies in a final effort to locate matching birth records. However, changes in preliminary results are expected to be very small in virtually all States. Final tabulations currently planned will make available completeness data for urban and rural residents and for various demographic charac-

Poliomyelitis in the United States, 1951

By C. C. DAUER, M.D.

A decrease of approximately 15 percent in both the incidence of poliomyelitis and its estimated death rate in the United States in 1951 is indicated by comparison of provisional data with 1950 figures. Five thousand fewer cases were reported than in 1950, and the estimated death rate, based on a 10-percent sample, was 0.9 per 100,000 population as compared with 1.1 for 1950. (Comparative data for 1946-51 are given in table 1.)

The distribution of poliomyelitis cases by counties in 1951 is shown on the map. The largest area of relatively high incidence was centered in the Colorado-Utah-Wyoming tri-

angle, but it also included portions of adjacent States. In 1950, the area of highest incidence was adjacent to and east of this area.

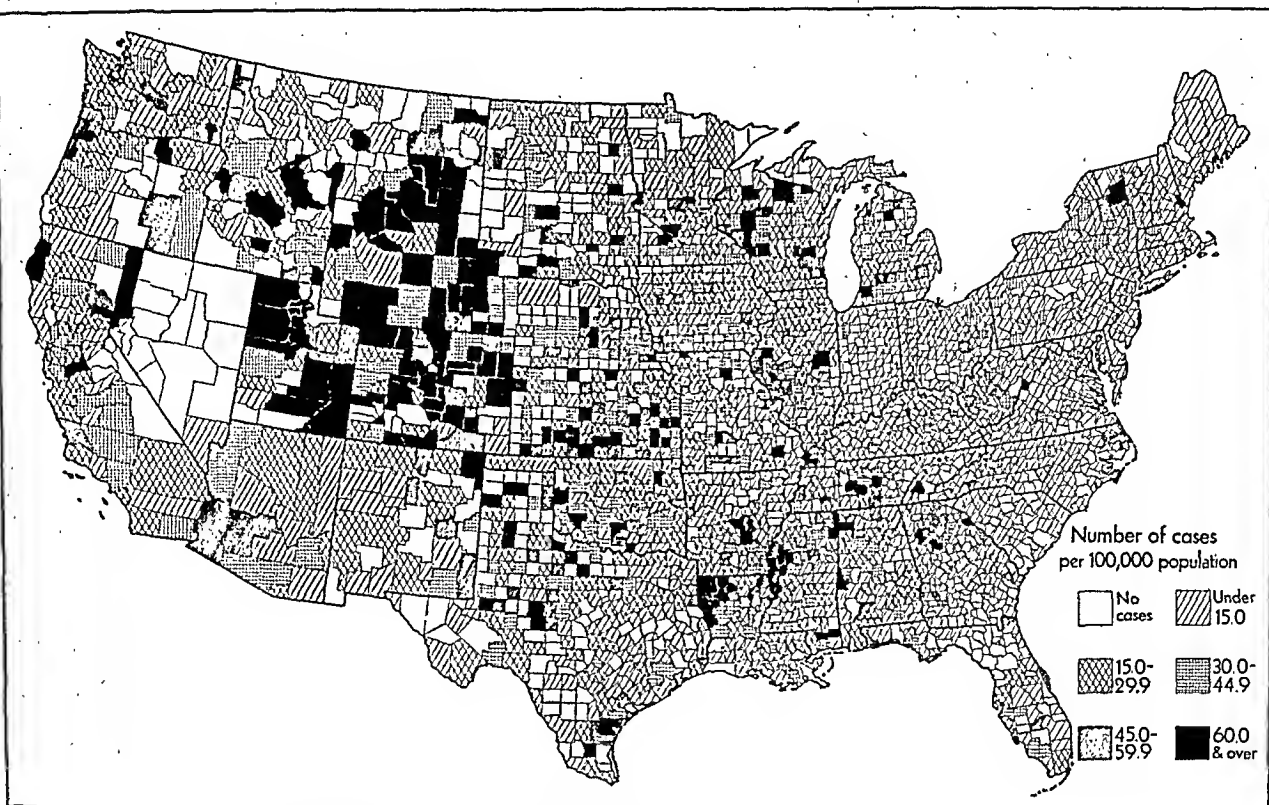

There were smaller areas of epidemicity in southeast Kansas, Wisconsin, Illinois, Missis-

Distribution of poliomyelitis in the United States, 1951.

Mississippi, Louisiana, Georgia, Tennessee, and Texas. In some counties in these areas the incidence rates were comparable to those found in a few counties in the larger area.

The county having the highest incidence rate was Pueblo County, Colo.; 280 cases were reported and the rate was 310 per 100,000 population. Sunflower County, Miss., reported 148 cases, with a rate of 264; Sawyer County, Wis., reported 26 cases, with a rate of 252. Several counties in the northwestern part of Louisiana had incidence rates varying from 107 to 225 cases per 100,000 population. These rates, however, were all well below the 1950 rate of 810 in Wythe County, Va.

Cases of poliomyelitis had been reported in all the counties mentioned above in several of the years immediately prior to 1951 and in some of the counties in each of the 5 years from 1946 to 1950. Thus, relatively high rates of incidence of the disease may occur in a small area, such as a county, where the infection has been present in recognizable form in the years immediately prior to the epidemic period.

The 1951 incidence rates of poliomyelitis for the various States ranged from about 2 cases per 100,000 population in Rhode Island to 84 in Utah (see table 2). The median rate for the 48 States and the District of Columbia was 18.8, which was also the incidence rate for the United States as a whole.

Utah, Colorado, and Wyoming, the center of the largest epidemic area, were the three States having the highest incidence rates. Although relatively high, the rates in these States were much below the rates for Minnesota (117.3) in 1946 and South Dakota (150.6) in 1948, and slightly less than the rate for Idaho in 1949. Colorado had relatively high rates in 2 of the 5 years immediately preceding 1951, 75.9 in 1946 and 53.5 in 1949. In both Utah and Wyoming incidence rates were moderately high in 3 of the 5 years.

Included in the five States having the highest incidence rates in 1951 was Wisconsin, in the East North Central section, and Kansas, in the West North Central section.

physicians in Mercer County. In Allegheny County, where nearly half of the study area's physicians are concentrated, 39 percent replied.

Comparison of the age distribution of those who replied with that of all the active private practitioners in the area (table 2) shows the two distributions to be similar. As has been found in other studies, the younger men showed a greater disposition to reply. The distribution of specialties among those who replied is also similar to that of the total (table 3). More complete returns would have strengthened the conclusions coming out of this analysis. However, in view of the representative character of the replying physicians—at least with respect to age and specialty—the proportion of questionnaires returned appears adequate. Fur-

thermore, the findings are consistent with those observed elsewhere.

Weekly Patient Load of General Practitioners

The average weekly patient loads (different individuals) of general practitioners in western Pennsylvania and the results of previous studies are shown in table 4. Part-specialists, those who are interested in, but do not limit their practices exclusively to, a special field of medicine, are included here as general practitioners.

Because of differences found elsewhere between rural and urban physicians, the data for Pennsylvania are grouped as follows in order to arrive at some approximation here of rural-urban differences: Pittsburgh, Allegheny County (including Pittsburgh), other metropolitan counties, and other counties. The other metropolitan counties consist of the four counties in the study area—Blair, Cambria, Erie, and Lawrence—which contain cities of 50,000 persons or more. The other counties are the remaining 22 in this study.

General practitioners in this area saw an average of 107 patients during the study week, 83 in the office, 8 in the hospital, and 16 in the patient's home. Pittsburgh and other Allegheny County physicians reported a lower average patient load than did the physicians in the remainder of the area. This agrees with previous findings that general practitioners in predominately urban areas have a lower patient load than those practicing in more rural places. In the present instance, the difference in totals is largely accounted for by the differences in number of patients seen in the office.

The patient load for all general practitioners in Pennsylvania is about the same as that observed in Georgia in December 1942, and somewhat lower than was found in the District of Columbia in September 1942 and in Maryland in October 1942. However, these three studies were made about a year after the United States entered World War II, when almost a quarter of the physicians in active private practice had been drawn into the armed forces (?). The present patient load in western Pennsylvania is appreciably higher than it was in the District of Columbia in June 1947. Then, in the Dis-

trict, the bulk of the physicians in service had been released, including many new physicians who had been trained during the war years, and the ratio of physicians to population had returned to its prewar level. Thus, the physicians in this area apparently are nearly as busy as physicians were in three other areas after 1 year of war, and busier than physicians in post-war Washington, where the receipt of medical services is at least as high as anywhere else in the country but where the ratio of physicians to population is also very high.

The size of the standard deviations that accompany these averages reflects the wide varia-

tion in patient load among general practitioners and among all physicians. The extent of this variation is about the same here as in the other areas studied, indicating the consistency of these data with the findings elsewhere.

One of the major elements contributing to the total variation in the patient load is the variation according to age of physician. That age is a factor in size of practice has been clearly demonstrated in the earlier studies. It re-emphasizes the inadequacy of the relative number of physicians as an index of services available to the population.

In Allegheny County and in the nonmetropolitan counties, the maximum patient load is found in the age group 35-44 years, with a decrease to a minimum in the group 65 years and over (fig. 1). This is the same pattern observed in all the previous studies and is reflected in a similar pattern of income among general practitioners (8).

The findings in relation to other metropolitan counties do not follow the same pattern. In these counties, the older physicians reported as high a patient load as the younger physicians. No explanation can be offered at this time except perhaps that this pattern may be a consequence of a higher demand for services in these counties than in the other parts of the study area.

Weekly Patient Load of Specialists

As has been found in other studies, the patient load among physicians who limit their practices to special fields of medicine tends on the whole to be somewhat lower than among general practitioners, although ophthalmology and otorhinolaryngology, which are combined, and pediatrics appear to be exceptions. For these specialties and for neurology and psychiatry, the physicians in Allegheny County have a higher patient load than the same specialists in the other counties. For the other specialties the reverse is true (table 5).

Patient Load and Number of Physicians

There has been a tendency to assume that physicians must be overworked in areas where

they are scarce and that those in communities with a relatively large number of physicians have little to do. As was pointed out in an earlier paper (9), patient load is not necessarily related to the supply of physicians.

Comparison of patient load (table 6, col. 1) with the ratio of physicians to population (table 1) reveals that in general there is little association between the two items. Armstrong and Indiana Counties, for example, have ratios of 57 and 61 physicians per 100,000 population, respectively, yet the general practitioners of Armstrong County, which has fewer physicians, reported a patient load of 110 as contrasted with 145 in Indiana County. At the same time, the general practitioners in counties with more than 90 physicians per 100,000 persons—Allegheny, Erie, McKean, and Warren—reported below-average patient loads. If one can generalize from these findings, it would appear that in counties with relatively few physicians, the patient load may be large or small, while in counties with a relatively large

number of physicians, the patient load tends to be low.

The small association between patient load and relative numbers of physicians is seemingly reflected in the absence of association between patient load and per capita income in the individual counties. Low patient loads are found in both wealthy and poor counties, in the former because they tend to have a large number of physicians and in the latter because of the low demand for services. Thus, average patient load was 92 in Allegheny, the wealthiest county in the group, and 81 in Greene, one of the poorer counties.

The conclusion from these findings must be that neither patient load nor supply of physicians will alone measure the demand for medical services. The latter indicates the medical resources potentially available to the population while the former measures the degree of activity of these physicians. The two together are necessary in order to obtain a measure of services actually received and should constitute

Table 4. Average weekly patient load of general practitioners ¹ by place of practice

the basis for appraising the effective demand to be expected from a population.

Such a measure can be acquired directly from the consumers of medical care by interview, but this is a more costly and time-consuming method and would not be expected to yield more accurate results from a practical standpoint.

Services Per Person

An estimate of the total volume of services obtained in one week by the population can be calculated by multiplying the average patient load by the number of physicians practicing in the community. Multiplication by 50, assuming that the physician's year is composed of 50 weeks, will yield an estimate of the total number of services received in one year. For purposes of comparison among different populations, total services are best reduced to a per capita basis by dividing total volume by the size of the population (table 6, col. 2).

There is marked variation among the counties, the range in annual services per person being 2.6 to 6.4. However, in 11 of the 27 counties the annual number of services fell between 4.0 and 5.0 per person; in the majority of counties the rate was more than 4.0 services.

Similar calculations in the previous studies

show that for all of Maryland and for urban Georgia the estimated annual services per person were 4.7 and 4.9, respectively, which are close to the average of 4.4 here. As would be expected, the rates for Baltimore and the District of Columbia were much higher, 5.9 and 6.2. These high rates of services reflect two factors: (a) the greater availability of medical personnel and the higher demand that accompanies higher income and educational levels; and (b) the movement of patients for medical care toward the metropolitan centers.

This factor of movement has to be taken into account if a real understanding is to be sought of the differences between areas in the amount of medical services received. Such information is available in the present study since the physicians supplied data on place of residence of

Figure 2. Scatter diagram showing adjusted services per person and ratio of physicians to population (each point represent a county).

the patients seen on one particular day. On the basis of these data, an adjustment for movement of patients from one county to another was made possible (table 6, col. 3).

The counties which contain large cities and attract patients from elsewhere show a decrease in number of services per person, while the more rural counties show an increase. The reason is that the data now apply to the residents of the respective counties. The unadjusted figure may be compared to birth and death rates by place of occurrence, while the adjusted figures are analogous to these rates by place of residence. The net result of this adjustment is to diminish the differences between counties. The great majority of counties, 18 of the 27, now show 4.0 to 5.0 services per person. Although rank order of the counties remains about the same after the adjustment, some striking changes occur in the actual rates of certain counties. For example, the rate for Armstrong

changes from 3.2 to 4.2. This marked increase is related to the extent to which the population travels to other counties, Allegheny County in particular, for medical care.

The rate, services per person, is calculated from the number of physicians and their patient load. As we have seen, there is very little association between these two. It remains now to determine how either of them or both are related to number of services per person.

Figure 2 is a scatter diagram showing adjusted services per person and ratio of physicians to population; each point represents a county. It can be seen from the figure that a tendency exists for services to increase as the ratio goes up. Where the supply of physicians is high, the number of services received per person also tends to be high. However, the scatter of the points shows that the degree of association is not sufficiently strong to permit one to assume that whenever there is a

larger supply of physicians, more services will be received by the population. Indeed, a recent study of two counties in New York State (10) demonstrated that the reverse could occur. In one county with 97 general physicians per 100,000 persons, 54 percent of a sample of residents reported a visit to the physician in the study year. The other county had 85 such physicians per 100,000 persons, yet 62 percent of the population reported at least one visit. The difference between percentages is attributed by the authors of the study largely to differences in the accessibility and geographic distribution of general physicians within the two counties. All these findings point to the limitations of the ratio of physicians to population as a measure of medical services.

An association is also found in western Pennsylvania between patient load and services per person, but the degree is even smaller.

¹ Since these are based on the number of different individuals seen in one week and not on visits, they underestimate somewhat the true number of services.

² Fewer than 20 percent of the physicians reported.

To some extent both of these findings are to be expected in view of the lack of association between patient load and ratio of physicians to population. To calculate or estimate services per person, both sets of data are needed.

Summary and Discussion

The findings of this study of patient load among the physicians of 27 counties of western Pennsylvania may be summarized as follows:

1. The average weekly patient load (different individuals) of general practitioners in October 1950 was 107. The patient load was lower in Allegheny County and Pittsburgh than in the rest of the study area.

2. In general, the age pattern was the same as that observed in other studies, with peak patient load among physicians in the 35-44 age group.

3. Patient load of the individual counties was not appreciably related to per capita income or to the relative number of physicians in the county.

4. The estimated number of services per person, adjusted for the movement of patients from one county to another, was found to lie between 4.0 and 5.0 per year in the majority of counties.

5. The average number of services per person was associated with number of physicians in the county and to a lesser degree with patient load.

These findings have a bearing on several aspects of medical care problems. In the first place, they reveal that physicians, in this area at least, are as busy on the average as physicians were in several other parts of the country at the end of 1942 after a substantial number of physicians had been drawn from civilian life into the armed forces. Since no earlier data are available for the study area, we cannot say whether the work load of physicians has been increasing or not. However, a patient load nearly equivalent to that observed here was cause for anxiety among practicing physicians of the areas studied during the war. It would, therefore, appear that, by and large, the physicians in the present study area are working at nearly full capacity. To what extent this work load can be increased cannot be determined without more intensive investigation. One

item of information on this point is that in April 1945 the average weekly patient load of general practitioners in the District of Columbia had reached a peak of 133, and had become a matter of deep concern to the Medical Society of the District.

In view of the current discussions on the need for more physicians, further studies of patient load, both actual and potential, would go far to clarify the issues.

The patient load enables us to estimate the amount of physician services received by a population. It is this volume of services, rather than the number of physicians in the population, which should be used as an index of the adequacy of the amount of medical services that a population is receiving. This is important when we are considering problems of medical care generally, but it is particularly important now when we are faced with the possibility of having to withdraw large numbers of physicians from the civilian population. Under such circumstances, we must consider whether or not to decrease the services received by the civilian population, or if we wish to maintain the services at their present level, how far the number of physicians can be reduced and the patient load of the remaining physicians increased. In either instance we must know the number and kinds of these services, the number of physicians, and their patient load.

Dr. McCoy, Former Director of NIH

Dr. George W. McCoy, for 22 years director of the Hygienic Laboratory (now the National Institutes of Health) of the Public Health Service died in Washington, D. C., April 2, at the age of 75.

Dr. McCoy entered the Public Health Service in 1900. He served as director of the U. S. Plague Laboratory at San Francisco, 1908-11; director of the U. S. Leprosy Investigation Station in Hawaii, 1911-15; and director of the Hygienic Laboratory, 1915-37.

A leading authority on leprosy, Dr. McCoy was also widely recognized for his contributions in the fields of plague, tularemia, psittacosis, postvaccination complications, and biologics control. In collaboration with Dr. Charles W. Chapin, Dr. McCoy isolated, identified, and cultivated the causative organism of tularemia.

After his retirement from the Public Health Service in 1937, Dr. McCoy was professor of preventive medicine and public health and acting dean of the Louisiana State University School of Medicine until 1948.

Dr. McCoy received his doctor of medicine degree from the University of Pennsylvania Medical School and his doctor of science degree from Louisiana State University. Honors he received included the Sedgwick Memorial Medal of the American Public Health Association.

Measuring the Extent of Immunization

— in Grand Rapids and Kent County, Michigan —

By GRACE ELDERING, Sc.D., and PEARL L. KENDRICK, Sc.D.

In 1950, a study to determine the extent of immunization procedures and of prenatal and postnatal services was made in Grand Rapids, Mich., a city of less than 200,000 population, where unusual emphasis has been placed upon immunization procedures for many years. Questionnaires were mailed to mothers of all babies aged 12 and 13 months, with follow-up by telephone or nurse's visit when replies were not received by mail. This method of sampling, which was similar to that used in a study in Philadelphia in 1949, and described by Kandle and Goetz (1, 2), appeared to be reliable and useful, especially with regard to patterns of practice, and had the added advantage of being simple and inexpensive. We hope that, in addition to the actual information obtained, further experience with the method, this time in a smaller community, will aid in evaluating its general usefulness as a public health tool.

The area for study was extended to include not only the city of Grand Rapids but also the surrounding territory comprising Kent County,

Dr. Eldering is a bacteriologist at the western Michigan section of the Michigan Department of Health Laboratories, Grand Rapids, Mich.; Dr. Kendrick is with the School of Public Health, University of Michigan, Ann Arbor, Mich.

The City Health Department of Grand Rapids, the Kent County Health Department, and the Michigan Department of Health collaborated in this study.

in which about half the population is rural. The survey was conducted under the auspices of the city and county health departments. The pertussis field study group at the western Michigan section laboratory of the Michigan Department of Health, consisting of a nurse and a clerk, supervised by the laboratory section chief, and an additional nurse half-time for 4 months, formed the central working group for the study.

Selection of Sample

The total population of the study area was estimated at 286,235, with 176,235 in Grand Rapids and 110,000 in Kent County outside the city, subsequently referred to in this report as city and county, respectively. The sample for study included all the babies born during January, February, and March 1949.

Separate card files were prepared for city and county, and the names of the baby and mother, the address, race, and date of birth, obtained from the official birth records, were recorded for each baby born during the 3 months selected. The files were checked against the death records to remove from the sample the names of babies that had died. One hundred and ninety-two illegitimate babies were also excluded. The files used in the study contained 1,728 names, 1,071 for the city and 657 for the county, comprising 24 percent of the total births for the year. At the time the questionnaires were mailed, mid-February 1950, the infants studied were from 11 to 13 months old.

The questionnaire was essentially like the one used in the Philadelphia study (2).

Table 1. Number and percent of replies received before and after telephone follow-up and nurses' visits

Questionnaires	Total		Grand Rapids		Kent County	
	Number	Percent	Number	percent	Number	Percent
Mailed.....	1,728	100.0	1,071	100.0	657	100.0
Answered.....	1,547	89.5	964	90.0	583	88.7
By mail, no follow-up.....	1,026	59.3	634	59.2	392	59.6

By nurse's visit.....	181	10.5	149	13.9	32	4.9
Not answered.....	181	10.5	107	10.0	74	11.3

Preparation of the Community

Following the procedure used in the Philadelphia study, the importance of community-wide cooperation was stressed, not only to assure the success of the project, but also to broaden the area of its educational effect. The fact that in Grand Rapids there was a background of 25 years of cooperative work by the Michigan Department of Health Laboratory and the local health departments, including a series of field studies, facilitated the project. In the weeks just preceding mailing of the questionnaires every effort was made to acquaint the public with the survey objectives. The plan was outlined to the physicians through the Kent County Medical Society and the local Pediatrics Society. Through the health chairman of the Parent-Teachers Association, announcements were made to their local groups. In mid-February the two daily newspapers in the city and the weekly papers in the county carried news stories and a few weeks later followed up with feature stories. The local radio

stations made spot announcements during the week the questionnaires were sent out.

Returns

Three weeks after mailing the questionnaires, telephone follow-up was started. The two study nurses and the clerk reached as many as possible of the mothers from whom replies had not been received. In those instances in which the original form was reported lost or not received, a second questionnaire was sent. Three weeks later the nurses began home visits in the city. The two study nurses, with the help of the bureau of public health nurses, made the calls within the city. The county calls were left until last because of road conditions, and were made entirely by the two study nurses.

The number and percent of replies are summarized in table 1.

Of the 1,728 questionnaires sent by mail, 1,071 were to mothers living in the city of Grand Rapids and 657 were to residents of Kent County. The 1,026 replies received by mail

Table 2. Summary of replies to questions concerning immunization against pertussis

¹ Three times σ percent (assuming simple randomness).

without follow-up comprised 59.3 percent of the total, with the city and county returns in almost the same proportion. Telephone follow-up increased the replies to 79 percent, and nurses' visits brought in 10.5 percent more, making the final percentage 89.5. The proportions of replies received for Grand Rapids and for Kent County were essentially the same, 90 percent compared with 88.7. The relatively greater effectiveness of the telephone follow-up in the county is explained by the fact that greater effort was made to reach rural residents by telephone in order to save the time and expense of a nurse's visit. Replies were not obtained from 181 mothers (10.5 percent of the sample). The families could not be located, and it was presumed that they had moved or that the original address had been in error. The replies totaled 1,547, or 21 percent of the births during 1949, whereas in the Philadelphia survey, 61 percent of the questionnaires were returned by mail without follow-up and the total replies comprised 84 percent of the sample, which in turn represented 12.6 percent of the births for the year.

Analysis of Replies

The replies to the questionnaires were tabulated separately for the city of Grand Rapids and for the surrounding Kent County area. Within the city the four geographic divisions—northeast, northwest, southeast, and southwest—were analyzed separately, but the observed differences were so small that only the combined data are presented here.

The sample was composed entirely of white persons except for 45 Negroes in the city and 2

Indians, 1 in the city and 1 in the county. Thirty-five of the questionnaires concerning Negro infants were returned. While the sample was small, the replies suggested that in comparison with the white babies fewer of the Negro babies had been immunized, and that a larger percentage of the Negro babies had been taken to public clinics.

Pertussis Immunization

The replies to the question concerning pertussis immunization are summarized in table 2. The percentages are based upon the number of questionnaires that were answered.

The replies indicate that 83.6 percent of the Grand Rapids babies had received one or more immunizing injections against pertussis, while in the county the percentage was 72.5. Private physicians gave 71.8 percent of the inoculations in the city and 90.3 percent in the county. The results of the corollary question concerning the number of doses are summarized in table 3.

According to the table, 55.2 percent of the Grand Rapids babies and 48.5 percent of those in the county had at least two doses of pertussis vaccine. For the entire area the percentage was 52.7. Nine and eight-tenths percent were stated to have had one dose, and for 16.9 percent the number of doses was not stated.

Subsequent to the tabulation and analysis of the data from the questionnaires, further information was obtained concerning the pertussis immunization status of the babies in the Grand Rapids sample. Since the results of the second follow-up have significance with respect to both major objectives of the study, namely, actual information and evaluation of the method, the additional data are included here.

Table 3. Summary of replies related to number of doses of pertussis vaccine

Was the baby immunized?	How many doses?	Total area		Grand Rapids		Kent County	
		Number	Percent	Number	Percent	Number	Percent
Yes.....	1.....	152	9.8	107	11.1	45	7.7
	2 or more.....	815	52.7	532	55.2	283	48.5
	Not stated.....	261	16.9	166	17.1	95	16.3
No.....		309	20.0	154	15.9	155	26.6
Not stated.....		10	.6	5	.5	5	.9

We were concerned first by the large number of replies in which the number of doses was not stated, although the main question, "Has the baby been immunized . . .?" was answered affirmatively. Of the 166 who gave such replies in Grand Rapids, we were able to investigate 124 further: 38 were found in the city health department immunization clinic files and 86 who had been immunized by private physicians were checked by telephone call to mother or doctor. All of these 124 babies had a record of two or more injections of combined diphtheria toxoid and pertussis vaccine at the time of the survey.

We were also interested in the babies stated to have had one dose of pertussis vaccine. According to the questionnaires, many of these had received smallpox vaccination, usually not given until diphtheria and pertussis injections are completed. Of the 107 Grand Rapids babies in this category (table 3), 79 were located again. Twenty-one were found in the city immunization file and of these, 13 had completed the series at the time of the survey. Of those immunized by their own doctor, 58 were found again. Seventeen had had only one injection, 2 had received two injections, and 39, the full course of inoculations at the time of the survey. Referring now to table 3, if we add to the 532 with "two or more" doses of vaccine the 124 from the "not stated" group and the 54 from the "one dose" group we have 710 with at least two doses, or 74 percent of the Grand Rapids sample. This is obviously still less than the true figure since 72 of the "not stated" and "one dose" groups were not followed up the second time. Why so many mothers either left unanswered the question on

number of doses, or gave the incorrect answer of "one dose" when the child had actually had the complete course we do not know. A different wording of the questionnaire, such as "How many injections?" might have been more successful.

Diphtheria Immunization

The replies to the second question, which concerned diphtheria immunization, are summarized in table 4.

Since combined diphtheria toxoid and pertussis vaccine had been in general use in this area for several years, similar replies would be expected to the first two questions, and the differences observed in the figures in tables 2 and 4 are small. For the whole area, 75.8 percent of the babies were stated to have received diphtheria immunization. The Philadelphia survey indicated that in that city 63 percent of the white babies and 41 percent of the Negro babies had two or more immunizing injections against diphtheria.

Smallpox Vaccination

The replies to the question on smallpox vaccination indicated a relatively low level of immunization at the age sampled—27 percent in the county and 40 percent in Grand Rapids, or 35 percent in the entire area. This is explained by the fact that the recommended procedure here advises smallpox vaccination at 1 year of age.

Prenatal Care

The replies to the questions regarding prenatal care indicated almost identical patterns in the city and the more rural area within the

Table 4. Summary of replies to questions concerning diphtheria immunization

Immunization	Total area		Grand Rapids		Kent County	
	Number	Percent	Number	Percent	Number	Percent
Yes.....	1, 172	75. 8±3. 7	769	79. 7±4. 4	403	69. 1±7. 0

Table 5. Analysis of replies to question concerning pertussis immunization from the Grand Rapids area, according to those obtained by mail, telephone call, and nurse's visit

Replies	Total	Yes		No		Not stated	
		Number	Percent	Number	Percent	Number	Percent
Total.....	964	805	83.5 ± 3.6	154	16.0	5	0.5
By mail.....	634	570	89.9	62	9.8	2	.3
By telephone.....	181	131	72.4	47	26.0	3	1.7
By nurse's visit.....	149	104	69.8	45	30.2	0	.0

¹ Three times σ percent.

county. In answer to the query, "Who took care of you during your pregnancy?" 98 percent of the mothers stated "private physician," 1 percent (18 mothers) stated "hospital clinic," and 1 percent left the question unanswered. As to the time of first visit to doctor or clinic, 78 percent went during the first trimester, 18 percent during the second, 2 percent in the last trimester, and 2 percent did not state time of visit. With regard to nursing care, 15 percent of the Kent County mothers and 18 percent of the Grand Rapids mothers stated they had been visited by a public health nurse during their pregnancy. About one-fourth of those receiving visits had only one, while 50 percent had received from two to four visits.

Postnatal Care

The replies to the questions regarding postnatal care revealed several differences between the two areas under study. Eighty percent of the Grand Rapids mothers said they had been visited by a nurse after the birth of their baby, compared with 47 percent of the Kent County mothers. In this connection it should be explained that the community health nurses make visits only within the metropolitan area of Grand Rapids.

At least 85 percent of those receiving nurse's visits stated that the nurse called during the first month after the baby's birth; 34 percent recorded only one visit, and 55 percent stated there had been from two to four.

Eight percent of the mothers in both areas stated that their babies had received no medical check-up. An additional 4 percent left this question unanswered. Among those who had medical attention, the number of check-ups

varied, with more for city than county babies. Approximately 50 percent had from one to four, while roughly one-fourth had from five to nine. Medical check-ups for 84 percent of the Grand Rapids babies were made by private physicians, 1 percent by a hospital, and 13 percent by the baby clinic. In the county, 92 percent were made by a private doctor, 2 percent by a hospital, and 4 percent by the baby clinic.

Comments by Mothers

A postscript to the questionnaire, asking for suggestions for the improvement of child-care services, brought responses from 124 mothers, half in the city and half in the county. About one-third of the statements expressed only gratitude and commendation. There were 23 definite complaints, most of them because of "lack of nursing service." Twenty mothers requested help on specific problems, such as need for transportation to an immunization clinic or advice concerning a sick baby. Of 20 constructive suggestions from city mothers and 29 from mothers in the county, 16 asked for more nursing service, 13 cited the need for making known the available services, and 20 requested more immunization clinics and well-baby clinics.

Comparative Value of Follow-Up

The question arises as to the value of the follow-up by telephone and nurse's visit to obtain replies not returned directly by mail. For information as to whether it was worth the additional time, effort, and money required to gather the telephone and visit data, the replies to the question on pertussis immunization for

the Grand Rapids sample were analyzed with respect to the method by which they were obtained. Table 5 shows the breakdown of the 964 replies to the questionnaires sent to 1,071 mothers.

The percentages of affirmative replies by mail, telephone, and nurse's visit were 89.9, 72.4, and 69.8, respectively, indicating a statistically significant difference. These results suggest that the data concerning the 107 babies for whom questionnaires were not returned would also have been different from the data returned directly by mail and emphasize the limitations of the survey method.

Summary and Conclusions

1. A survey of the immunization status of 1-year-old infants and of certain nursing services to mothers and babies was conducted in Grand Rapids and Kent County, Mich. The sample was selected and data obtained according to the method of Kandle and Goetz, using a mailed questionnaire with follow-up by telephone calls and nurses' visits.

2. Replies were received from 89.5 percent of the mothers to whom questionnaires were sent. The sample of 1,547 replies represented 21.5 percent of the births during 1949.

3. According to the replies, two or more injections of pertussis vaccine had been given to 52.7 percent of the infants. As a validation procedure, this information was amplified and corrected by checking with the city health department immunization files and by additional follow-up by telephone. The corrected figure for the city was about 74 percent. The survey method was considered inadequate for obtaining such detailed information as number of injections.

4. In Grand Rapids, 71.8 percent of the babies who had been immunized received their pertussis immunization from private physicians and 26 percent from the health department clinic; in the county these percentages were 90.3 and 8.5, respectively.

5. Prenatal care was given almost entirely by private physician rather than hospital clinic or health department. Fifteen percent of the mothers in the county and 18 percent in the city had been visited by a public health nurse during their pregnancy.

6. The pattern of postnatal care varied somewhat in the two areas; more nursing calls were made in the city than in the county, and a higher percentage of the city babies were taken to baby clinics for medical check-ups.

7. The comments by the mothers showed a surprising lack of knowledge of the health services available in the community. As the study progressed there was obviously an increased interest which, although not subject to measurement, indicated that the survey had educational value.

ACKNOWLEDGMENT

Acknowledgment is made to Dr. Robert Rothermel for his assistance in the setting up of the study; to Dr. Roscoe Kandle for making available unpublished tabulations of the Philadelphia study; and to the press, the radio, and the Parent-Teachers Association of the city of Grand Rapids for their help with publicity.

Home Accident Prevention Activities

By FREDERICK S. KENT, M.P.H., and MADELINE PERSHING, M.A.

Much has been written and many discussions have been held on the problem of home accidents, their prevention, and their relationship to public health. The continuing high accidental injury and death rates represent to conscientious health workers a negation of many of the positive advances that have been made in the prevention of disease during the past several decades. Because of the growing awareness among health workers of the urgency of the problem, it seems appropriate to review past endeavors in home accident prevention, to reconsider present problems in the light of history, and to contemplate the future.

The Accident Problem

Mortality

Accidents, as a cause of death, were relatively less important in the early part of this century when communicable diseases were on the rampage. However, as the combined efforts of the public health and medical professions slowly, and in some instances dramatically, tamed these major killers, accidents rose in relative rank until now they stand among the leaders.

For many years the only figures available on accidents were those derived from analysis of death certificates. In view of the need for more specific reporting, a standard accident reporting system was developed in 1925 by the National Safety Council, as an approach to

national uniformity in reporting of fatal accidents (1). The Census Bureau began publishing data on deaths from home accidents in 1935. None of these activities included the gathering of statistics on nonfatal accident.

With better reporting of figures on fatal home accidents, and realization of the magnitude of the problem by public health agencies, the next step was the standard epidemiological approach—what, how, why, where, and when—to form the basis for planning a practical home accident prevention program.

To define the accident problem more clearly, the National Office of Vital Statistics, Public Health Service, developed a general accident-fatality form in 1949 which included a part of the standard death certificate plus epidemiological information desired on all non-motor-vehicle accidents. Since motor vehicle accidents already were being investigated and reported, this additional type of information appeared necessary to focus the total accident problem more clearly. The form was offered to the States as an aid in studying their own accident problem, and 18 States used it during the 1½ years in which it was available. In 1950, the National Office of Vital Statistics, wishing to ally their efforts more closely to other special efforts then being made by the Division of Sanitation of the Public Health Service, replaced the general accident-fatality form with the more specific home accident fatality form now used in 10 States.

Morbidity

Although all of these studies and evaluations stressed the importance of accidents in public health work, it was appreciated that they by no means presented the total problem.

Mr. Kent is chief of the home accident prevention unit, for which Miss Pershing is nursing consultant, in the Division of Sanitation of the Bureau of State Services, Public Health Service.

There was a need to supplement such information with more facts and figures on the extent and circumstances of nonfatal home accidents.

Probably the first study to obtain data on nonfatal accidents was the National Health Survey of 1935-36 (2). The survey's findings indicated the magnitude and public health importance of home accidents and suggested the need for more intensive studies of specific causes of accidents, particularly from the point of view of developing methods of prevention. (The oft-used ratio of 150 nonfatal home accidents to each fatal one was based on the data gathered in this survey.) The survey produced enlightening information not previously available, but the sample selected represented only 3.6 percent of the 1930 urban population of the United States. The information elicited on accidental injury concerned an even smaller percentage. Also, the survey did not include rural homes, thus omitting consideration of many conditions having an accident potential not ordinarily found in urban dwellings.

Since the collection of statistics is not an end in itself, the facts gathered from both morbidity and mortality studies are the stepping stones which categorical activities of the health department should use to plan and evaluate home accident prevention programs.

At the Local Level

The National Safety Council, the Subcommittee on Accident Prevention of the American Public Health Association, the American Red Cross, and the Public Health Service have all recognized that the prevention of home accidents is essentially a local problem.

State health departments in conducting studies of home accidents have found that the chief types, in relative importance, follow a common pattern. However, although falls, burns, and poisoning strike in similar ratios in most areas, the causative factors may vary significantly in different localities. Such differences require variation in methods of control for specific application to specific problems.

Experience has illustrated the advisability and practicability of using the "rifle" approach of hitting the major problems, rather than the "shot-gun" approach of scattering our efforts

in the hope that some of them may be productive. The home accident prevention program must be directed to those causes or to those age groups constituting the bulk of the home accident problem. Funds, personnel, and time are too scarce to be wasted on less significant aspects of the problem.

The statistical basis for such a "rifle" approach was first utilized by Dr. Earl G. Brown while he was commissioner of health for Kansas. He initiated the collection, tabulation, and analysis of statistics relating to fatal accidents, on a continuing basis, at the State level, thereby demonstrating the practical value of this philosophy.

It is important that as essential as statistics and epidemiological investigations of fatal accidents are, they still must be supplemented with detailed information on the types and causes of the greater number of home accidents resulting in injury but not in death. This supplemental information has been, and is being, obtained in several ways. By no means do we have the perfect method yet, but each procedure, despite limitations, adds to our store of knowledge.

Among such supplemental sources of information are the hospitals in a community. Red Cross chapters in large cities like Washington, D. C., Atlanta, Ga., and Kansas City, Mo., have learned that hospitals will cooperate in conducting studies of nonfatal home accidents. Reports prepared by the hospital staff, using data collected from the out-patient and in-patient services and emergency rooms, are made available to control agencies. They represent one contribution which hospitals can make as members of the community team. While these statistics do not represent a cross section of the accident problem, they are indicative of areas in which activity is needed. It is well worth the health department's effort to obtain the cooperation of the planning and operating levels of a hospital in supplying such data.

Case Evaluation

It is obvious that analysis of records on fatalities and injuries will not present the whole problem. The goal should be the investigation of every accident, whether or not it results in injury. But although the desirability of studying each accident experience, regardless of its

end, cannot be questioned, we must realize the impracticability of this procedure.

Of four individuals who may experience the same accident, for example tripping on a torn stair carpet, one may fall and be killed; another may fall and fracture a leg or arm; the third person may not fall, but in twisting, may sprain an ankle; while the fourth may catch himself and go on his way without injury of any kind. Undoubtedly, the circumstances in the first case will be remembered by witnesses, in the second case by the individual himself for a long period of time; in the third case for a week or so; and in the last case no longer than a few minutes or hours.

Therefore, we must set a criterion, or definition, for "reportable" experiences that will be remembered and recounted on interview to give us a basis for comparing the findings of studies and for evaluating the effectiveness of programs. The National Safety Council and the Public Health Service recommended the criterion now used in demonstration projects and other programs in which nonfatal accidents are being studied: "A reportable home accident is one which causes an interruption of normal activity for a period of at least 24 hours beyond the time of injury." There are, of course, exceptions to the rule, but these are few in number and tend to strike a balance.

Community Demonstrations

In 1948, the W. K. Kellogg Foundation became interested in the home accident problem. Following discussions with the Public Health Service, the Foundation's division of public health recommended that its board of trustees appropriate funds for a demonstration program in home accident prevention by a local health department. Dr. Winston B. Prothro, health officer, Kalamazoo (Mich.) City-County Health Department expressed interest and submitted an application for a grant outlining a comprehensive program for investigating the home accident prevention problem and developing preventive measures. In September 1948, a grant was made to the Kalamazoo Health Department "to demonstrate the possibility of effecting a significant reduction of mortality and morbidity caused by home accidents" (3).

The demonstration program at Kalamazoo is

now in its fourth year. The results of the early period of this demonstration led to the Public Health Service recommendation that additional demonstrations be undertaken in different areas of the United States in health departments of varying size and composition. The Kellogg Foundation favored the proposal, and after reviewing applications from 41 local health departments, selected three to undertake demonstration programs for periods of 3 to 5 years. In August 1951, demonstrations were started by health departments in Cambridge, Mass., San Jose, Calif., and Mansfield-Richland County, Ohio.
